

2×2 W, Filterless, Stereo, Class-D Audio Amplifier with ALC and I²C

SSM2380

FEATURES

Filterless, stereo, Class-D amplifier with Σ-Δ modulation 2 W into 4 Ω load and 1.4 W into 8 Ω load at 5.0 V supply with <1% total harmonic distortion plus noise (THD + N) Highly configurable I2C interface for gain adjust, automatic level control (ALC), and ultralow EMI emissions mode MODE pin can disable I2C interface for more traditional stereo amplifier configuration Stereo-to-mono mixer option via I2C control 93% efficiency at 5.0 V, 1.4 W into 8 Ω speaker Signal-to-noise ratio (SNR): >100 dB Single-supply operation from 2.5 V to 5.5 V Ultralow shutdown current: 20 nA Short-circuit and thermal protection Pop-and-click suppression Available in 16-ball, 2.0 mm × 2.0 mm WLCSP

APPLICATIONS

Mobile phones MP3 players Portable electronics

GENERAL DESCRIPTION

The [SSM2380](http://www.analog.com/SSM2380) is a fully integrated, high efficiency, stereo, Class-D audio amplifier. It is designed to maximize performance for mobile phone applications. The application circuit requires a minimum of external components and operates from a single 2.5 V to 5.5 V supply. It is capable of delivering 2 W of continuous output power with <1% THD + N driving a 4 Ω load from a 5.0 V supply.

The SSM2380 features a highly flexible I^2C interface with many useful settings. Using the I²C control interface, the gain of the SSM2380 can be selected from 1 dB to 24 dB (plus mute) in 47 steps with no external components. Other features accessed from the I²C interface include independent left/right channel shutdown, variable ultralow EMI emission control mode, automatic level control (ALC) for high quality speaker protection, and stereo-to-mono mixing operation.

The SSM2380 features a high efficiency, low noise modulation scheme that requires no external LC output filters. The modulation continues to provide high efficiency even at low output power. The SSM2380 operates with 93% efficiency at 1.4 W into 8 Ω or with 85% efficiency at 2 W into 4 Ω from a 5.0 V supply and has an SNR of >100 dB.

Spread-spectrum pulse density modulation is used to provide lower EMI-radiated emissions compared with other Class-D architectures. An added benefit of spread-spectrum Σ-Δ modulation is that no synchronization (SYNC) is needed when using multiple Class-D amplifiers. For applications that require long speaker cables (>10 cm), the SSM2380 includes a user-selectable ultralow EMI emissions mode that eliminates the need for EMI filters at the Class-D outputs.

The SSM2380 has a micropower shutdown mode with a typical shutdown current of 20 nA. Shutdown is enabled by applying a logic low to the \overline{SD} pin or through an optional independent channel soft shutdown via I²C.

The device also includes pop-and-click suppression circuitry. This suppression circuitry minimizes voltage glitches at the output during turn-on and turn-off, reducing audible noise on activation and deactivation.

The fully differential inputs of the SSM2380 provide excellent rejection of common-mode noise on the input. Input coupling capacitors can be omitted if the dc input common-mode voltage is approximately V_{DD}/2.

The SSM2380 is specified over the commercial temperature range of −40°C to +85°C. It has built-in thermal shutdown and output short-circuit protection. It is available in a 16-ball, 2 mm × 2 mm wafer level chip scale package (WLCSP).

THEORY OF OPERATION **OVERVIEW**

The SSM2380 stereo, Class-D audio amplifier features a filterless modulation scheme that greatly reduces the external component count, conserving board space and, thus, reducing system cost. The SSM2380 does not require an output filter but, instead, relies on the inherent inductance of the speaker coil and the natural filtering of the speaker and human ear to fully recover the audio component of the square wave output.

Most Class-D amplifiers use some variation of pulse-width modulation (PWM), but the SSM2380 uses Σ-Δ modulation to determine the switching pattern of the output devices, resulting in a number of important benefits.

- Σ-Δ modulators do not produce a sharp peak with many harmonics in the AM frequency band, as pulse-width modulators often do.
- Σ - Δ modulation provides the benefits of reducing the amplitude of spectral components at high frequencies, that is, reducing EMI emissions that might otherwise be radiated by speakers and long cable traces.
- The SSM2380 does not require external EMI filtering for twisted speaker cable lengths shorter than 10 cm. If longer speaker cables are used, the SSM2380 has an emission suppression mode that allows significantly longer speaker cable.
- Due to the inherent spread-spectrum nature of Σ-Δ modulation, the need for modulator synchronization is eliminated for designs that incorporate multiple SSM2380 amplifiers.

Using the I²C control interface, the gain of the SSM2380 can be selected from 1 dB to 24 dB (plus mute) in 47 steps with no external components and fixed input impedance. Other features accessed from the I²C interface include the following:

- Independent left/right channel shutdown
- Variable ultralow EMI emission control mode
- Automatic level control (ALC) for high quality speaker protection
- Stereo-to-mono mixing operation

The SSM2380 also offers protection circuits for overcurrent and overtemperature protection.

POP-AND-CLICK SUPPRESSION

Voltage transients at the output of audio amplifiers can occur when shutdown is activated or deactivated. Voltage transients as low as 10 mV can be heard as an audio pop in the speaker. Clicks and pops can also be classified as undesirable audible transients generated by the amplifier system and, therefore, as not coming from the system input signal. Such transients may be generated when the amplifier system changes its operating mode. For example, the following may be sources of audible transients: system power-up and power-down, mute and unmute, input source change, and sample rate change.

The SSM2380 has a pop-and-click suppression architecture that reduces these output transients, resulting in noiseless activation and deactivation.

OUTPUT MODULATION DESCRIPTION

The SSM2380 uses three-level, Σ-Δ output modulation. Each output can swing from GND to V_{DD} and vice versa. Ideally, when no input signal is present, the output differential voltage is 0 V because there is no need to generate a pulse. In a real-world situation, noise sources are always present.

Due to the constant presence of noise, a differential pulse is generated, when required, in response to this stimulus. A small amount of current flows into the inductive load when the differential pulse is generated.

Most of the time, however, the output differential voltage is 0 V, due to the Analog Devices, Inc., three-level, Σ-Δ output modulation. This feature ensures that the current flowing through the inductive load is small.

When the user wants to send an input signal, an output pulse (OUTx+ and OUTx−) is generated to follow the input voltage. The differential pulse density (V_{OUT}) is increased by raising the input signal level. [Figure 35](#page-13-1) depicts three-level, Σ-Δ output modulation with and without input stimulus.

OPERATING MODES

The SSM2380 has three unique operating modes, controlled by the MODE pin. When MODE (Ball C2) is connected to GND, the SSM2380 operates in I²C control mode; Ball C3 and Ball C4 function as SCK and SDA for the I²C input. In I²C control mode, the user has full control of all internal registers of the SSM2380 (see [Table 11](#page-24-1)).

When MODE (Ball C2) is connected to VDD, the SSM2380 operates in gain select mode; Ball C3 and Ball C4 function as the gain select pins, GAIN0 and GAIN1. All ALC and emission control features are disabled in gain select mode, and the user can set the gain to 6 dB, 12 dB, 18 dB, or 24 dB only.

When MODE (Ball C2) is not connected (floating), the SSM2380 operates in ALC mode; Ball C3 and Ball C4 function as EDGE and ALCTH. In ALC mode, the default gain is 18 dB. The user can enable or disable the emission control (EMI) feature by connecting EDGE (Ball C3) to VDD or GND. In addition to emission control, the ALC is activated. The user must connect a resistor from ALCTH (Ball C4) to GND. This resistor allows the user to limit the output level to any setting from 45% to 90% of V_{DD} .

Table 6. MODE Pin Selection Guide

SSM2380 Ball			
Ball C2 (MODE)	Ball C3	Ball C4	Operating Mode
High (connected to VDD)	GAINO	GAIN1	Gain select mode
Low (connected to GND)	SCK	SDA	I ² C control mode
Open (floating)	FDGF	AI CTH	ALC mode

ALC MODE OPERATION

When MODE is not connected (floating), the SSM2380 is in ALC mode, disabling the I²C interface. In ALC mode, the user has control of only two functions: setting the ALC threshold voltage and activating or deactivating the emission limiting circuitry.

Setting the ALC Threshold Voltage

To set the ALC threshold voltage, connect ALCTH (Ball C4) to GND with a series resistor. [Figure 36](#page-14-1) shows the relationship between the R_{TH} resistor setting and the output voltage limit as a percentage of the supply rail.

To calculate the resistor value, use the following equations:

Limit (%) = 100 × $(R_{EXT} + 53)/(2.2 \times R_{EXT} + 58)$ kΩ

$$
R_{EXT}=(53-58\times Limit/100)/(2.2\times (Limit/100-1))\%
$$

For example, to set an 80% limit,

 $R_{EXT} = (53 - 58 \times 80/100)/(2.2 \times (80/100 - 1) \text{ k}\Omega$

Therefore, 8.7 k Ω is required.

Maximum output power is derived from V_{TH} using the following equation:

$$
P_{OUT} = \frac{\left(\frac{(Limit \times V_{DD})/100}{\sqrt{2}}\right)^2}{R_{SP}}
$$

where R_{SP} is the speaker impedance.

In ALC mode, the attack, hold, and release times associated with ALC operation are at fixed levels, as indicated in [Table 7](#page-14-2).

Table 7. Attack, Hold, and Release Times for ALC Mode

Time	Duration
Attack Time	$256 \,\mu s$ (per 0.5 dB step)
Hold Time	90 ms to 120 ms (nonadjustable)
Release Time	128 ms (per 0.5 dB step)

Activating or Deactivating the Emission Limiting Circuitry

To activate or deactivate the emission limiting circuitry, connect EDGE (Ball C3) to GND or to VDD. When EDGE is connected to GND, the SSM2380 is in normal operating mode, deactivating the emission limiting function. The device operates with maximum efficiency and noise level performance in this setting. The user can also pass FCC Class B emission testing with 10 cm twisted pair speaker wire for loudspeaker connection.

If longer speaker wire is desired, connect the EDGE pin to VDD to activate the emission limiting circuitry. The trade-off is slightly lower efficiency and noise performance. The penalty for using the emission control circuitry is far less than the decreased performance observed when using a ferrite bead based EMI filter for emission limiting purposes.

GAIN SELECT MODE OPERATION

When MODE is connected to VDD, the SSM2380 is in gain select mode, disabling the I²C interface. The ALC and emission limiting functions are also disabled. Ball C3 and Ball C4 function as the gain select pins, GAIN0 and GAIN1. [Table 8](#page-15-1) shows the user-selectable gain settings for the SSM2380.

Table 8. Gain Settings in Gain Select Mode

I 2 C CONTROL MODE OPERATION

When MODE is connected to GND, the SSM2380 operates in I²C control mode, enabling Ball C3 and Ball C4 to act as SCK and SDA for the I²C input. In I²C control mode, the user has full control of all features of the SSM2380 (see [Table 11](#page-24-1)).

- Gain control: 48-step, left/right independent control (ALC is off)
- ALC control (limiter/compressor): configurable attack and release times; configurable threshold voltage (16 level settings, 64% to 96% of V_{DD}); optional fixed-power mode (does not track rail)
- Output stage: active emissions edge rate control (four settings)
- Mixer: option to send left channel input to both left and right channel outputs or to send right channel input to both outputs

AUTOMATIC LEVEL CONTROL (ALC)

Automatic level control (ALC) is a function that automatically adjusts amplifier gain to generate the desired output amplitude with reference to a particular input stimulus. The primary use for the ALC is to protect an audio power amplifier or speaker load from the damaging effects of clipping or current overloading. This is accomplished by limiting the output amplitude of the amplifier upon reaching a preset threshold voltage. Another benefit of the ALC is that it makes sound sources with a wide dynamic range more intelligible by boosting low level signals, while in turn limiting very high level signals.

Before activating the ALC by setting the ALC_EN bit (Bit 7 in Register R4), the user has full control of the left and right channel PGA gain (programmable in Register R0 and Register R1). After the ALC is activated $(ALC_EN = 1)$, the user has no control over the gain settings in Register R0 and Register R1; the left channel PGA gain is locked into the device and controls the gain for both the left and right channels. To change the gain, the user must reset the ALC_EN bit to 0 and then load the new gain settings.

[Figure 37](#page-15-2) shows the input vs. output and gain characteristics of the ALC that is implemented in the SSM2380.

Figure 37. Input vs. Output and Gain Characteristics

When the input level is small and below the ALC threshold value, the gain of the amplifier stays at the preset gain setting. When the input exceeds the ALC threshold value, the ALC gradually reduces the gain from the preset gain setting down to 1 dB.

ALC Compression and Limiting Modes

The ALC implemented on the SSM2380 has two operation modes: compression and limiting. When the ALC is triggered for medium-level input signals, the ALC is in compression mode. In this mode, an increase of the output signal is one-third the increase of the input signal. For example, if the input signal increases by 3 dB, the ALC reduces the amplifier gain by 2 dB and thus the output signal increases by only 1 dB.

As the input signal becomes very large, the ALC transitions to limiting mode. In this mode, the output stays at a given threshold level, V_{TH}, even if the input signal grows larger. As an example of limiting mode operation, when a large input signal increases by 3 dB, the ALC reduces the amplifier gain by 3 dB and thus the output increases by 0 dB. When the amplifier gain is reduced to 1 dB, the ALC cannot reduce the gain further, and the output increases again. This is because the total range of the ALC operation has bottomed out due to extreme input voltage at high gain. To avoid potential speaker damage, the maximum input amplitude should not be large enough to exceed the maximum attenuation (to a level of 1 dB) of the limiting mode.

Attack Time, Hold Time, and Release Time

When the amplifier input signal exceeds a preset threshold, the ALC reduces amplifier gain rapidly until the output voltage settles to a target level. This target level is maintained for a certain period. If the input voltage does not exceed the threshold again, the ALC increases the gain gradually.

The attack time is the time taken to reduce the gain from maximum to minimum. The hold time is the time that the reduced gain is maintained. The release time is the time taken to increase the gain from minimum to maximum. These times are shown in [Table 9](#page-16-0).

¹ The attack time and release time can be adjusted using the ¹²C interface. The hold time cannot be adjusted.

Soft-Knee Compression

Often performed using sophisticated DSP algorithms, soft-knee compression provides maximum sound quality with effective speaker protection. Instead of using a fixed compression setting prior to limiting, the SSM2380 allows for a much more subtle transition into limiting mode, preserving the original sound quality of the source audio. [Figure 38](#page-16-1) to [Figure 40](#page-16-2) show the various soft-knee compression settings. If desired, compression can be disabled. When compression is disabled, the part operates in limiter-only mode.

ALC Soft Transition

The ALC operation of the SSM2380 incorporates techniques to reduce the audible artifacts associated with gain change transitions. First, the gain is changed in small increments of 0.5 dB. In addition to this small step size, the rate of gain change is reduced, proportional to the attack time setting. This feature drastically reduces and virtually eliminates the presence of zipper noise and other artifacts associated with gain transitions during ALC operation. [Figure 41](#page-16-3) shows the soft transition operation.

MIXER MODE

When I²C control mode is activated, the user can send left channel input to both left and right channel outputs or send right channel input to both outputs. This is achieved by selecting Register R2, Bit 0 or Bit 1.

Using Mixer Mode with the ALC

If the ALC is enabled and the user also wishes to use the mixer operation, follow the guidelines in this section. Left channel gain controls the ALC; therefore, sending left channel input to the left and right channel outputs poses no problem for the ALC. However, to source the right channel input to the left and right channel outputs when using the ALC, the user must first load the left channel gain (Register R0, Bit 7).

With the ALC disabled, the user can also use the full mixer capability; that is, if the user wishes to mix the right and left inputs for both the right and left outputs, the ALC must be disabled. If the user needs both the mixing and ALC functions, the left or right channel must be muted to avoid problems.

When the ALC is active, the following options are acceptable:

- Left output $=$ left input; right output $=$ right input
- Left output $=$ left input; right output $=$ left input
- Left output $=$ right input; right output $=$ right input

To use the following options, the ALC must be disabled:

- Left output = left input + right input; right output = right input
- Left output = left input; right output = left input + right input
- Left output = $left input + right input; right output = left$ input + right input

APPLICATIONS INFORMATION **LAYOUT**

As output power increases, care must be taken to lay out printed circuit board (PCB) traces and wires properly among the amplifier, load, and power supply. A good practice is to use short, wide PCB tracks to decrease voltage drops and minimize inductance. Ensure that track widths are at least 200 mil for every inch of track length for lowest DCR, and use 1 oz or 2 oz copper PCB traces to further reduce IR drops and inductance. A poor layout increases voltage drops, consequently affecting efficiency. Use large traces for the power supply inputs and amplifier outputs to minimize losses due to parasitic trace resistance.

Proper grounding guidelines help to improve audio performance, minimize crosstalk between channels, and prevent switching noise from coupling into the audio signal. To maintain high output swing and high peak output power, the PCB traces that connect the output pins to the load, as well as the PCB traces to the supply pins, should be as wide as possible to maintain the minimum trace resistances. It is also recommended that a large ground plane be used for minimum impedances.

In addition, good PCB layout isolates critical analog paths from sources of high interference. High frequency circuits (analog and digital) should be separated from low frequency circuits. Properly designed multilayer PCBs can reduce EMI emissions and increase immunity to the RF field by a factor of 10 or more compared with double-sided boards. A multilayer board allows a complete layer to be used for the ground plane, whereas the ground plane side of a double-sided board is often disrupted by signal crossover.

If the system has separate analog and digital ground and power planes, the analog ground plane should be directly beneath the analog power plane, and, similarly, the digital ground plane should be directly beneath the digital power plane. There should be no overlap between analog and digital ground planes or between analog and digital power planes.

INPUT CAPACITOR SELECTION

The SSM2380 does not require input coupling capacitors if the input signal is biased from 1.0 V to V_{DD} – 1.0 V. Input capacitors are required if the input signal is not biased within this recommended input dc common-mode voltage range, if high-pass filtering is needed, or if a single-ended source is used. If highpass filtering is needed at the input, the input capacitor and the input resistor of the SSM2380 form a high-pass filter whose corner frequency is determined by the following equation:

$$
f_C = 1/(2\pi \times R_{IN} \times C_{IN})
$$

The input capacitor can significantly affect the performance of the circuit. Not using input capacitors degrades both the output offset of the amplifier and the dc PSRR performance.

In I²C control mode, the input impedance changes depending on the gain setting from Register R0 and Register R1 (LGAIN[5:0] and RGAIN[5:0] bits). [Table 10](#page-18-1) shows the R_{IN} value for each PGA gain setting.

Table 10. Input Impedance for I2 C Control Mode

POWER SUPPLY DECOUPLING

To ensure high efficiency, low total harmonic distortion (THD), and high PSRR, proper power supply decoupling is necessary. Noise transients on the power supply lines are short-duration voltage spikes. Although the actual switching frequency is typically 325 kHz, these spikes can contain frequency components that extend into the hundreds of megahertz.

The power supply inputs must be decoupled with a good quality, low ESL, low ESR capacitor, usually of approximately 4.7 μF. This capacitor bypasses low frequency noises to the ground plane.

For high frequency transient noises, use a 0.1 μF capacitor as close as possible to the VDD pins of the device. Placing the decoupling capacitors as close as possible to the SSM2380 helps to maintain efficient performance.

I 2 C INTERFACE

The I²C interface provides access to the user-selectable control registers and operates with a 2-wire interface.

Each control register consists of 16 bits, MSB first. Bits[B15:B9] are the register map address, and Bits[B8:B0] are the register data for the associated register map.

SDA generates the serial control data-word, and SCK clocks the serial data. The I2 C bus address (Bits[A7:A1]) is 0x31 (01100010 for write and 01100011 for read). Bit A0 is the designated read/write bit.
