

High voltage high- and low-side driver for automotive applications

Datasheet - production data

Features

- High voltage rail up to 550 V
- dV/dt immunity ± 50 V/nsec in full temperature range
- Driver current capability
 - 400 mA source
 - 650 mA sink
- Switching times 50/30 nsec rise/fall with 1 nF load
- CMOS/TTL Schmitt-trigger inputs with hysteresis and pull down
- Internal bootstrap diode

- Outputs in phase with inputs
- Interlocking function
- AECQ100 automotive qualified

Applications

- Drive inverters for HEV and EV
- HID ballasts, power supply units
- Motion driver for home appliances, factory automation, industrial drives

Description

The A6387 is a high voltage device, manufactured with the BCD™ “offline” technology. It is a single chip half-bridge gate driver for N-channel Power MOSFETs or IGBTs. The high-side (floating) section is designed to stand a voltage rail of up to 550 V. The logic inputs are CMOS/TTL compatible for easy interfacing of the microcontroller or DSP.

1. The circuit provides less than 1 V on the LVG and HVG pins (at I_{sink} = 10 mA). This allows the omitting of the “bleeder” resistor connected between the gate and the source of the external MOSFET normally used to hold the pin low.

3 Electrical characteristics

3.1 AC operation

$V_{CC} = 15\text{ V}$; $T_J = -40\text{ }^\circ\text{C} \div 125\text{ }^\circ\text{C}$, unless otherwise specified.

1. R_{DS(on)} is tested in the following way:

$$R_{DS(on)} = \frac{(V_{CC} - V_{BOOT1}) - (V_{CC} - V_{BOOT2})}{I_1(V_{CC}, V_{BOOT1}) - I_2(V_{CC}, V_{BOOT2})}$$

where I₁ is pin 8 current when V_{BOOT} = V_{BOOT1}, I₂ when V_{BOOT} = V_{BOOT2}.

2. V_{BO} = V_{boot} - V_{out}.

4 Input logic

The A6387 input logic is V_{CC} (17 V) compatible. An interlocking feature is offered (see [Table 7](#)) to avoid undesired simultaneous turn-on of both power switches driven.

5 Bootstrap driver

A bootstrap circuitry is needed to supply the high voltage section. This function is normally accomplished by a high voltage fast recovery diode (*Figure 5 a*). In the A6387 device a patented integrated structure replaces the external diode. It is realized by a high voltage DMOS, driven synchronously with the low-side driver (LVG), with a diode in series, as shown in *Figure 5 b*. An internal charge pump (*Figure 5 b*) provides the DMOS driving voltage.

C_{BOOT} selection and charging

To choose the proper C_{BOOT} value the external MOS can be seen as an equivalent capacitor. This capacitor C_{EXT} is related to the MOS total gate charge:

Equation 1

$$C_{EXT} = \frac{Q_{gate}}{V_{gate}}$$

The ratio between the capacitors C_{EXT} and C_{BOOT} is proportional to the cyclical voltage loss. It must be:

$$C_{BOOT} \gg C_{EXT}$$

For example: if Q_{gate} is 30 nC and V_{gate} is 10 V, C_{EXT} is 3 nF. With $C_{BOOT} = 100$ nF the drop would be 300 mV.

If HVG must be supplied for a long period, the C_{BOOT} selection must take into account also the leakage and quiescent losses.

For example: HVG steady-state consumption is lower than 100 μ A, therefore, if HVG T_{ON} is 5 ms, C_{BOOT} must supply 0.5 μ C to C_{EXT} . This charge on a 1 μ F capacitor means a voltage drop of 0.5 V.

The internal bootstrap driver offers a big advantage: the external fast recovery diode can be avoided (it usually has very high leakage current).

This structure can work only if V_{OUT} is close to GND (or lower) and, in the meantime, the LVG is on. The charging time (T_{charge}) of the C_{BOOT} is the time in which both conditions are fulfilled and it must be long enough to charge the capacitor.

The bootstrap driver introduces a voltage drop due to the DMOS R_{DSon} (typical value: 125 Ω). This drop can be neglected at low switching frequency, but it should be taken into account when operating at high switching frequency.

Equation 2 is useful to compute the drop on the bootstrap DMOS:

Equation 2

$$V_{drop} = I_{charge} R_{dson} \rightarrow V_{drop} = \frac{Q_{gate}}{T_{charge}} R_{dson}$$

where Q_{gate} is the gate charge of the external power MOS, R_{DSon} is the ON-resistance of the bootstrap DMOS, and T_{charge} is the charging time of the bootstrap capacitor.

For example: using a power MOS with a total gate charge of 30 nC, the drop on the bootstrap DMOS is about 1 V, if the T_{charge} is 5 μs . In fact:

Equation 3

$$V_{drop} = \frac{30nC}{5\mu s} \cdot 125\Omega \sim 0.8V$$

V_{drop} should be taken into account when the voltage drop on C_{BOOT} is calculated: if this drop is too high, or the circuit topology doesn't allow a sufficient charging time, an external diode can be used.
