

# Low Cost, Triple Differential Drivers for Wideband Video

# Data Sheet **[AD8141/](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)**

### <span id="page-0-0"></span>**FEATURES**

**Triple, high speed differential drivers 255 MHz, −3 dB large signal bandwidth 65 MHz, 0.1 dB flatness 1150 V/μs slew rate 12 ns settling time Single 5 V or split supply operation Fixed gain of 2 Internal common-mode feedback network Output balance error −50 dB at 50 MHz [AD8142 h](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)as integrated sync-on-common-mode circuitry High-Z output when disabled Differential-to-differential or single-ended-to-differential operation High isolation between amplifiers: −100 dB at 10 MHz Low power: 44 mA at 5 V Available in space-saving packaging: 4 mm × 4 mm LFCSP** 

### <span id="page-0-1"></span>**APPLICATIONS**

**Keyboard-video-mouse (KVM) networking Video distribution Digital signage Security cameras** 

### **FUNCTIONAL BLOCK DIAGRAMS**

<span id="page-0-3"></span>

#### <span id="page-0-2"></span>**GENERAL DESCRIPTION**

The [AD8141 a](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)n[d AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) are triple, low cost, differential or single-ended-input-to-differential-output drivers. Each amplifier has a fixed gain of 2 to compensate for the attenuation of the line termination resistors. Th[e AD8141 a](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)nd [AD8142 a](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)re specifically designed for RGB signals but can be used for any type of signals. The amplifiers have very fast slew rate and settling time while being manufactured on a cost effective CMOS process. They are optimized for high resolution video performance with a 0.1 dB flatness of 65 MHz, which allows driving high resolution video over any type of UTP cable.

The drivers have an internal common-mode feedback loop that provides output amplitude and phase matching, achieving −50 dB balance error at 50 MHz and thereby suppressing evenorder harmonics and minimizing radiated electromagnetic interference (EMI).

The [AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) includes a unique sync-on-common-mode feature that allows the user to transmit balanced horizontal and vertical video sync signals over the three common-mode channels. Additionally, th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf) an[d AD8142 b](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)oth have a disable feature that, when asserted, produces high-Z outputs, allowing line isolation and easy multiplexing.

Th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf) an[d AD8142 a](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)re available in a 24-lead 4 mm  $\times$  4 mm LFCSP and operate over a temperature range of −40°C to +85°C. They can be used with th[e AD8145 t](http://www.analog.com/AD8145?doc=AD8141_8142.pdf)riple differential-to-singleended receiver, [AD8123 t](http://www.analog.com/AD8123?doc=AD8141_8142.pdf)riple equalizer, [AD8120 t](http://www.analog.com/AD8120?doc=AD8141_8142.pdf)riple delay line, and th[e AD8117 o](http://www.analog.com/AD8117?doc=AD8141_8142.pdf)[r AD8175](http://www.analog.com/ad8175?doc=AD8141_8142.pdf) crosspoint switches to produce a high resolution video distribution system.

## TABLE OF CONTENTS

### <span id="page-1-0"></span>**REVISION HISTORY**

### **7/2011—Revision 0: Initial Version**

### <span id="page-2-0"></span>**SPECIFICATIONS**

 $V_{S+} = 5$  V,  $V_{S-} = 0$  V,  $R_{L, dm} = 200 \Omega$ ,  $T_A = 25^{\circ}$ C,  $V_{OCM} = 1.5$  V [\(AD8141\)](http://www.analog.com/AD8141?doc=AD8141_8142.pdf),  $H_{SNC}$ ,  $V_{SNC}$ , and SYNC LEVEL = 0 V [\(AD8142\)](http://www.analog.com/AD8142?doc=AD8141_8142.pdf), unless otherwise noted.

<span id="page-2-1"></span>

### <span id="page-4-0"></span>ABSOLUTE MAXIMUM RATINGS

#### **Table 2.**

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

### <span id="page-4-1"></span>**THERMAL RESISTANCE**

 $θ<sub>JA</sub>$  is specified for the worst-case conditions, that is,  $θ<sub>JA</sub>$  is specified for the device soldered in a circuit board in still air.

**Table 3. Thermal Resistance with the Underside Pad Thermally Connected to a Copper Plane** 

### <span id="page-4-2"></span>**MAXIMUM POWER DISSIPATION**

The maximum safe power dissipation in th[e AD8141/](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) package is limited by the associated rise in junction temperature  $(T<sub>J</sub>)$  on the die. At approximately 150 $\degree$ C, which is the glass transition temperature, the plastic changes its properties. Even temporarily exceeding this temperature limit can change the stresses that the package exerts on the die, permanently shifting the parametric performance of th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[/AD8142.](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) Exceeding a junction temperature of 175°C for an extended period can result in changes in the silicon devices potentially causing failure.

The power dissipated in the package  $(P_D)$  is the sum of the quiescent power dissipation and the power dissipated in the package due to the load drive for all outputs. The quiescent power is the voltage between the supply pins  $(V<sub>s</sub>)$  times the quiescent current (IS). The load current consists of differential and common-mode currents flowing to the loads, as well as currents flowing through the internal differential and common-mode feedback loops. The internal resistor tap used in the commonmode feedback loop places a 12.5 kΩ differential load on the output. RMS output voltages should be considered when dealing with ac signals.

Airflow reduces  $\theta_{JA}$ . In addition, more metal directly in contact with the package leads from metal traces, through holes, ground, and power planes reduce the  $\theta_{JA}$ . The exposed pad on the underside of the package must be soldered to a pad on the PCB surface that is thermally connected to a PCB plane to achieve the specified  $\theta_{JA}$ .

[Figure 3](#page-4-4) shows the maximum safe power dissipation in the package vs. the ambient temperature for the 24-lead LFCSP (38°C/W) on a JEDEC standard 4-layer board with the underside paddle soldered to a pad that is thermally connected to a PCB plane.  $θ<sub>JA</sub>$  values are approximations.

<span id="page-4-4"></span>4-Layer Board

#### <span id="page-4-3"></span>**ESD CAUTION**

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

### <span id="page-5-0"></span>PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

### <span id="page-12-0"></span>**BASIC TEST CIRCUIT**

### <span id="page-13-0"></span>**TERMINOLOGY**

#### **Differential Voltage**

Differential voltage refers to the difference between two node voltages that are balanced with respect to each other. For example, i[n Figure 36,](#page-14-4) the output differential voltage (or output differential mode voltage) is defined as

$$
V_{OUT, dm} = (V_{OP} - V_{ON})
$$

Common-mode voltage refers to the average of two node voltages with respect to a common reference (usually the local ground). The output common-mode voltage is defined as

$$
V_{OUT,cm} = \frac{(V_{OP} + V_{ON})}{2}
$$

#### **Output Balance**

Output balance is a measure of how well the differential output signals are matched in amplitude and how close they are to exactly 180° apart in phase. Balance can be easily determined by placing a well-matched resistor divider between the differential output voltage nodes and comparing the magnitude of the signal at the divider's midpoint with the magnitude of the differential signal. By this definition, output balance error is the magnitude of the change in output common-mode voltage divided by the magnitude of the change in output differential-mode voltage in response to a differential input signal.

Output Balance Error = 
$$
\left| \frac{\Delta V_{OUT,cm}}{\Delta V_{OUT,dm}} \right|
$$

### <span id="page-14-0"></span>THEORY OF OPERATION

The differential drivers contained in th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf) and [AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) differ from conventional op amps in that they have two outputs whose voltages move in opposite directions. Like op amps, they rely on high open-loop gain and negative feedback to force these outputs to the desired voltages. Th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf) an[d AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) drivers make it easy to perform single-ended-to-differential conversion, common-mode level-shifting, and amplification of differential signals.

Previous differential drivers, both discrete and integrated designs, have been based on using two independent amplifiers and two independent feedback loops, one to control each of the outputs. When these circuits are driven from a single-ended source, the resulting outputs are typically not well balanced. Achieving a balanced output has generally required exceptional matching of the amplifiers and feedback networks.

DC common-mode level-shifting has also been difficult with previous differential drivers. Level-shifting has required the use of a third amplifier and feedback loop to control the output common-mode level. Sometimes, the third amplifier has also been used to attempt to correct an inherently unbalanced circuit. Excellent performance over a wide frequency range has proven difficult with this approach.

Each [AD8141/](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[AD8142 d](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)river uses two feedback loops to separately control the differential and common-mode output voltages. The differential feedback, set by the internal resistors, controls the differential output voltage only. The internal commonmode feedback loop controls the common-mode output voltage only. This architecture makes it easy to arbitrarily set the output common-mode level by simply applying a voltage to the V<sub>OCM</sub> input. The output common-mode voltage is forced, by internal common-mode feedback, to equal the voltage applied to the  $V_{OCM}$ input, while simultaneously balancing the differential output voltage. The  $AD8141$   $V_{OCM}$  inputs are available to the user, whereas the [AD8142 V](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)<sub>OCM</sub> inputs are internally connected to sync-on-commonmode circuitry that automatically imbeds the HSYNC and VSYNC signals on the three output common-mode voltages.

The overall driver architecture produces outputs that are highly balanced over a wide frequency range without requiring external components or adjustments. The common-mode feedback loop forces the signal component of the output common-mode voltage to be zeroed. The result is nearly perfectly balanced differential outputs of identical amplitude that are 180° apart in phase.

### <span id="page-14-1"></span>**ANALYZING AN APPLICATION CIRCUIT**

The drivers use two negative feedback loops, each with high open-loop gain, to force their differential and common-mode output voltages in such a way as to minimize the differential and common-mode input error voltages. The differential input error voltage is defined as the voltage between the differential inputs labeled  $V_{AP}$  and  $V_{AN}$  in [Figure 36.](#page-14-4) For most purposes, this voltage can be assumed to be zero. Similarly, the difference between the actual output common-mode voltage and the voltage applied to V<sub>OCM</sub> can also be assumed to be zero. Starting from these two assumptions, any application circuit can be analyzed.

### <span id="page-14-2"></span>**CLOSED-LOOP GAIN**

The differential mode gain of the circuit i[n Figure 36 c](#page-14-4)an be described by

$$
\left|\frac{V_{OUT,dm}}{V_{IN,dm}}\right| = \frac{R_F}{R_G} = 2
$$

where  $R_F$  = 2.0 kΩ and  $R_G$  = 1.0 kΩ nominally.

Figure 36. Circuit Definitions

### <span id="page-14-4"></span><span id="page-14-3"></span>**CALCULATING AN APPLICATION CIRCUIT'S INPUT IMPEDANCE**

The effective input impedance of a circuit such as that i[n Figure 36](#page-14-4)  at  $V_{IP}$  and  $V_{IN}$  depends on whether the amplifier is being driven by a single-ended or differential signal source. For balanced differential input signals, the differential input impedance, R<sub>IN, dm</sub> between the inputs  $V_{IP}$  and  $V_{IN}$  is simply

$$
R_{IN, dm} = 2 \times R_G = 2.0 \text{ k}\Omega
$$

In the case of a single-ended input signal (for example, if  $V_{IN}$ is grounded and the input signal is applied to  $V_{IP}$ ), the input impedance becomes

$$
R_{IN} = \left(\frac{R_G}{1 - \frac{R_F}{2 \times (R_G + R_F)}}\right) = 1.5 \text{ k}\Omega
$$

The input impedance of the circuit is higher than for a conventional op amp connected as an inverter because a fraction of the differential output voltage appears at the inputs as a common-mode signal, partially bootstrapping the voltage across the input resistor RG.

### <span id="page-15-0"></span>**INPUT COMMON-MODE VOLTAGE RANGE IN SINGLE-SUPPLY APPLICATIONS**

The driver inputs are designed to facilitate level-shifting of ground referenced input signals on a single power supply. For a singleended input, this implies, for example, that the voltage at  $V_{IN}$  in [Figure 36 i](#page-14-4)s 0 V when the amplifier's negative power supply voltage is also set to 0 V.

It is important to ensure that the common-mode voltage at the amplifier inputs,  $V_{AP}$  and  $V_{AN}$ , stays within its specified range. Because the V<sub>AP</sub> and V<sub>AN</sub> voltages are driven to be essentially equal by negative feedback, the amplifier's input common-mode voltage can be expressed as a single term, VACM. VACM can be calculated as

$$
V_{ACM} = \frac{V_{OCM} + 2V_{ICM}}{3}
$$

where  $V_{ICM}$  is the common-mode voltage of the input signal, that is,

$$
V_{ICM} = \frac{V_{IP} + V_{IN}}{2}
$$

### <span id="page-15-1"></span>**TERMINATING A SINGLE-ENDED INPUT**

Each driver has a nominal fixed gain of 2, with  $R_F = 2.0 \text{ k}\Omega$  and  $R<sub>G</sub> = 1.0 k\Omega$ . A typical single-ended video signal source applied to th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[/AD8142 i](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)nput has a maximum terminated output voltage of 0.7 V p-p and source resistance of 75  $Ω$ . Because the terminated output voltage of the source is 0.7 V p-p, the opencircuit output voltage of the source is 1.4 V p-p. The source shown in [Figure 37 i](#page-15-2)ndicates this open-circuit voltage. The following three steps illustrate how to terminate a signal from a typical single-ended 75  $\Omega$  video source.

1. The single-ended input impedance is calculated as  $R_{IN} = 1.5$  kΩ.

Figure 37. Calculating Single-Ended Input Impedance, R<sub>IN</sub>

<span id="page-15-2"></span>2. To match the 75  $\Omega$  source resistance, the termination resistor, R<sub>T</sub>, is calculated using R<sub>T</sub> $||1.125$  kΩ = 75 Ω. The closest standard 1% value for R<sub>T</sub> is 80.6 Ω.

Figure 38. Adding Termination Resistor  $R_{\text{I}}$ 

<span id="page-15-3"></span>3. It can be seen fro[m Figure 38](#page-15-3) that the effective  $R<sub>G</sub>$  in the upper feedback loop is now greater than the  $R<sub>G</sub>$  in the lower loop due to the addition of the termination resistors. To compensate for the imbalance of the gain resistors, a correction resistor  $(R<sub>TS</sub>)$  is added in series with  $R<sub>G</sub>$  in the lower loop. R<sub>TS</sub> is the closest 1% resistor to the Thevenin equivalent of the source resistance  $\rm R_S$  and the termination resistance  $R_T$ , equal to  $R_s||R_T$ .

1.  $R_{TH} = R_s || R_T = 38.8 \Omega$ , and  $R_{TS} = 38.3 \Omega$ . Note that  $V_{TH}$ is greater than 0.7 V p-p, which was obtained with  $R_T = 75$  $\Omega$  alone. The modified circuit with the Thevenin equivalent of the terminated source and R<sub>TS</sub> in the lower feedback loop is shown in [Figure 40.](#page-15-4) 

Figure 40. Thevenin Equivalent and Matched Gain Resistors

<span id="page-15-4"></span>[Figure 40 p](#page-15-4)resents a tractable circuit with matched feedback loops that can be easily evaluated.

It is useful to point out two effects that occur with a terminated input. The first is that the value of  $R<sub>G</sub>$  is increased in both loops, lowering the overall closed-loop gain. The second is that  $V<sub>TH</sub>$  is a little larger than 0.7 V p-p, as it is if  $R_T = 75 \Omega$  alone. These two effects have opposite impacts on the output voltage, and for large resistor values in the feedback loops, the effects essentially cancel each other out. For smaller  $R_F$  and  $R_G$ , however, the diminished closed-loop gain is not canceled completely by the increased  $V<sub>TH</sub>$ .

The desired differential output in this example is 1.4 V p-p because the terminated input signal is 0.7 V p-p and the closedloop gain = 2. The actual differential output voltage is equal to  $(0.725 \text{ V p-p})(2 \text{ k}\Omega/1038.3 \Omega) = 1.4 \text{ V p-p}$ . This illustrates how the two aforementioned effects cancel for large RF and RG.

### <span id="page-16-0"></span>**DRIVING A CAPACITIVE LOAD**

A purely capacitive load can react with the output impedance of the drivers to reduce phase margin, resulting in high frequency ringing in the pulse response. The best way to minimize this effect is to place the source termination resistors immediately at the amplifier outputs to minimize parasitic capacitances formed by unnecessarily long traces.

### <span id="page-16-1"></span>**DISABLE**

Th[e AD8141 a](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)n[d AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) have disable pins that, when pulled high, significantly reduce the power consumed while simultaneously placing the outputs in high-Z states. The disable feature can be used to multiplex two drivers. See [Figure 17,](#page-8-0) [Figure 19,](#page-9-0) and [Figure 22 f](#page-9-1)or the disabled input-to-output isolation, output impedance, and response performance. The threshold levels for the disable pin are listed i[n Table 1.](#page-2-1) 

An output glitch occurs whenever the disable feature is asserted or deasserted. See th[e Applications Information s](#page-17-0)ection for details.

### <span id="page-16-2"></span>**[AD8142 S](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)YNC-ON-COMMON-MODE**

Th[e AD8142 i](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)ncludes on-chip, sync-on-common-mode circuitry that encodes externally applied  $H_{\text{SYNC}}$  and  $V_{\text{SYNC}}$  signals onto the common-mode output voltages of each of the R, G, and B drivers. The circuit encodes the horizontal and vertical sync pulses in a way that results in low radiated energy. A simplified circuit that illustrates how the pulses are encoded is shown in [Figure 41.](#page-16-3)  For a more detailed description of the sync scheme, see the [Applications Information s](#page-17-0)ection.

The sync-on-common-mode circuit generates a current based on the voltage applied to the SYNC LEVEL input pin (Pin 18) with respect to the negative supply. With SYNC LEVEL input tied to VS−, the common-mode output of all drivers is set at 1.5 V above the negative supply. Using a resistor divider, a voltage can be applied between V<sub>S−</sub> and SYNC LEVEL that determines the maximum deviation of the common-mode outputs from their midsupply level. If, for instance, SYNC LEVEL –  $V_{S-} = 0.5$  V and the supply voltage is 5 V, then the common-mode outputs fall within an envelope of 1.5 V  $\pm$  0.5 V. The state of each V<sub>OUT, cm</sub> output based on the H<sub>SYNC</sub> and V<sub>SYNC</sub> inputs is determined by the equations defined in the [Applications Information s](#page-17-0)ection.

For the positive supplies between 2.5 V and 5 V, the sync-oncommon-mode circuit can be used by directly applying standard H<sub>SYNC</sub> and V<sub>SYNC</sub> signals to the respective [AD8142 i](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)nputs. These inputs adhere to standard logic thresholds (se[e Table 1](#page-2-1) for the exact levels). The H<sub>SYNC</sub> and V<sub>SYNC</sub> inputs, therefore, can be driven directly off the output of a computer video card without concern of being overdriven. The input path from the H<sub>SYNC</sub> and V<sub>SYNC</sub> inputs to the switches in the current mode level-shifting circuit are well matched to eliminate false switching transients. This maximizes common-mode balance and minimizes radiated energy.

<span id="page-16-3"></span>Figure 41. Sync-On-Common-Mode Simplified Circuit

## <span id="page-17-0"></span>APPLICATIONS INFORMATION

### <span id="page-17-1"></span>**DRIVING RGB VIDEO OVER CAT-5 CABLE**

Th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf) an[d AD8142 a](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)re devices whose foremost application is driving RGB and component video signals over unshielded twisted pair (UTP) cable in video distribution networks. Singleended video signals are easily converted to differential signals for transmission over the cable, and the internally fixed gain of 2

automatically compensates for the losses incurred by the source and load terminations. [Figure 42 s](#page-17-2)hows th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[/AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) in a triple, single-ended-to-differential application when driven from a 75 Ω video source.

<span id="page-17-2"></span>Figure 42[. AD8141/](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[AD8142 i](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)n Single-Ended-to-Differential Application on Single 5 V Supply (Sync Pulse Encoding Not Shown)

### <span id="page-18-0"></span>**SINGLE 5 V SUPPLY APPLICATION INFORMATION**

The [AD8141 a](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)n[d AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) require a nominal voltage of 5 V across their  $V_{S+}$  and  $V_{S-}$  power supply pins, and that their EPADs be connected to system ground; the voltage between  $V_{S+}$  and the local system ground must be greater than or equal to 2.5 V and less than or equal to 5 V. These requirements can be met by a single +5 V supply, or split supplies such as  $\pm$ 2.5 V, +3 V/−2 V, and so on. Operating th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf) an[d AD8142 w](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)ith ±2.5 V supplies provides considerable power savings compared with other drivers operating at  $\pm$ 5 V supplies, without any disadvantages with regard to input and output ranges in most cases.

The receivers used with th[e AD8141 a](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)nd [AD8142,](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) such as the [AD8145,](http://www.analog.com/AD8145?doc=AD8141_8142.pdf) [AD8143,](http://www.analog.com/AD8143?doc=AD8141_8142.pdf) [AD8123,](http://www.analog.com/AD8123?doc=AD8141_8142.pdf) an[d AD8128,](http://www.analog.com/AD8128?doc=AD8141_8142.pdf) generally operate with split supplies, ranging from  $\pm$ 5 V to  $\pm$ 12 V. The split supply arrangement results in a receiver input common-mode range that is centered at 0 V relative to the local ground reference and ranges to within a volt or two from each rail. Ground potential differences normally exist between the driver end and the receiver end, and these differences cause the relative common-mode voltages between the driver and receiver to shift. See [Figure 43](#page-18-1)  for an example.

I[n Figure 43,](#page-18-1)  $V_{R, CM} = V_{O, CM} + V_{SHIFT}$ . If  $V_{O, CM} = 0$  V and  $V_{SHIFT} =$ 2 V,  $V_{R, CM}$  is 2 V. This is because the receiver ground is shifted down by 2 V relative to the driver ground, and the commonmode level on the cable stays constant. It can be seen from this example that the most margin to absorb ground shifts exists when the center of the receiver input common-mode voltage range relative to its ground is the same as the output commonmode voltage of the driver with respect to its ground.

Most receivers operate with their input common-mode ranges centered at 0 V; therefore, the best case for the driver is to set its output common-mode voltage to 0 V. This is not possible for the [AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf) o[r AD8142 o](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)n a single 5 V supply, but it can be accomplished using split supplies. If a single 5 V supply is required, the rail-to-rail output allows th[e AD8141 o](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)utput common-mode voltage to be set to less than 1 V to be as close as possible to the ideal setting of 0 V. Whereas th[e AD8141 h](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)as uncommitted V<sub>OCM</sub> inputs, the [AD8142 h](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)as internal sync-encoding circuitry that fixes the nominal output common-mode voltage at 1.5 V above the negative rail. Each part has a resistive divider on the V<sub>OCM</sub> input that sets the nominal output common-mode voltage to 1.5 V above the negative rail when no external voltage is applied. The divider consists of a 8.75 kΩ resistor to V<sub>S+</sub> and a 3.75 kΩ resistor to V<sub>S−</sub>, forming a Thevenin equivalent load of 2.6 kΩ to 30% of the voltage across the supplies. In the single 5 V supply case, the Thevenin load voltage is 30% of 5 V above 0 V, or 1.5 V.

<span id="page-18-1"></span>Figure 43. End-to-End Common-Mode Shifts due to Ground Shifts

### <span id="page-19-0"></span>**[AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) SIGNAL LEVELS ON VARIOUS SUPPLIES**

[Figure 44 a](#page-19-2)n[d Figure 45](#page-20-2) illustrate the key video signal levels seen in typical applications operating on a single +5 V supply and ±2.5 V supplies; common-mode sync pulses are omitted from the circuit drawing for clarity but are shown in a separate waveform drawing of the signals directly at th[e AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) outputs, shown just below the associated circuit drawing. The sync pulses are common-mode, that is, they move in the same direction on each output polarity. I[n Figure 44 a](#page-19-2)n[d Figure 45,](#page-20-2) this means that the H<sub>SYNC</sub> pulses are either both green or both blue for the red and black video signals.

### <span id="page-19-1"></span>**DISABLE FEATURE**

When asserted, the disable feature minimizes quiescent current consumption and provides a high-Z output. It offers a convenient means to connect two driver outputs together in parallel to form a tristate multiplexed application. The disable feature can also be used to minimize quiescent current drawn when a particular device is not being used.

The disable pin is a binary input that controls the state of the [AD8141/](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[AD8142 o](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)utputs. Its binary input levels are compatible with most TTL and CMOS families (se[e Table 1 f](#page-2-1)or the logic levels). Th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[/AD8142 o](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)utput is disabled when the disable input is driven to its high state, and th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[/AD8142](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) operates in its normal fashion when the disable input is driven to its low state.

An unavoidable common-mode glitch occurs at the outputs when switching between disabled and enabled states and vice versa. The glitch lasts for a few tens of nanoseconds and is on the order of 2 V or 3 V. If the disable feature is used, it is recommended that common-mode protection be used on the receiver (see th[e AD8143](http://www.analog.com/AD8143?doc=AD8141_8142.pdf) data sheet for a detailed description of common-mode protection)

#### <span id="page-20-0"></span>**DRIVING MULTIPLE OUTPUTS**

Th[e AD8141](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)[/AD8142 c](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)an drive four parallel UTP cables (50  $\Omega$ differential load) with only 1.5% reduction in output swing (see [Figure 46\)](#page-20-3). As is expected, driving fewer parallel cables results in less output swing reduction.

Figure 46. Driving Four UTP Cables in Parallel

#### <span id="page-20-3"></span><span id="page-20-1"></span>**VIDEO SYNC-ON-COMMON-MODE [\(AD8142\)](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)**

In computer video applications, the horizontal and vertical sync signals are most often separate from the video information signals. For example, in typical computer monitor applications, the red, green, and blue (RGB) color signals are transmitted over separate cables, as are the vertical and horizontal sync signals. When transmitting these types of video signals over long distances on UTP cable, it is desirable to reduce the required number of physical channels. One way to do this is to encode the vertical and horizontal sync signals as weighted sums and differences of the output common-mode signals. The RGB color signals are each transmitted differentially over separate physical channels. The fact that the differential and common-mode signals are orthogonal allows the RGB color and sync signals to be separated at the channel's receiver.

Cat-5 type cable contains four balanced twisted-pair physical channels that can support both differential and common-mode signals. Transmitting typical computer monitor video over this cable can be accomplished by using three of the twisted pairs for the RGB and sync signals. Each color is transmitted differentially, one on each of the three pairs. The encoded sync signals are transmitted among the common-mode signals of each of the three pairs. To minimize EMI from the sync signals, the commonmode signals on each of the three pairs produced by the sync encoding scheme induce electric and magnetic fields that, for the most part, cancel each other. A conceptual block diagram of the sync encoding scheme is presented in [Figure 47.](#page-21-3) Because th[e AD8142 h](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)as the sync encoding scheme implemented internally, the user simply applies the horizontal and vertical sync signals directly to the appropriate inputs. As described in the [Theory of](#page-14-0)  [Operation](#page-14-0) section, th[e AD8142 a](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)ccepts ground-referenced logiclevel sync pulses (se[e Table 1 f](#page-2-1)or the exact levels). In many cases, the sync pulses can be applied directly from video card VGA connector outputs.

<span id="page-21-3"></span>The transmitted common-mode sync signal magnitudes are scaled by applying a dc voltage to the SYNC LEVEL input, referenced to the negative supply. The difference between the voltage applied to the SYNC LEVEL input and the negative supply sets the peak deviation of the encoded sync signals about the midsupply common-mode voltage. For example, with the SYNC LEVEL input set at  $V_{S-}$  + 500 mV, the deviation of the encoded sync pulses about the nominal midsupply common-mode voltage is nominally ±500 mV. The equations i[n Figure 47 d](#page-21-3)escribe how the V<sub>SYNC</sub> and H<sub>SYNC</sub> signals are encoded on each color's midsupply common-mode signal. In these equations, the weights of the VSYNC and  $H_{\text{SYNC}}$  signals are  $\pm 1$  (that is, +1 for high, -1 for low), and the constant, K, is equal to the peak deviation of the encoded sync signals.

[Figure 48 s](#page-21-4)hows how the sync signals appear on each commonmode voltage in a single 5 V supply application when the voltage applied to the SYNC LEVEL input is set to  $V_{S-}$  + 500 mV. Although the typical setting for the SYNC LEVEL voltage is 500 mV above the negative supply, it can be increased, if necessary, in extremely noisy environments. Increasing the SYNC LEVEL voltage too much has the potential to produce excessive EMI.

<span id="page-21-4"></span>Figure 48[. AD8142 S](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)ync-On-Common-Mode Signals in Single 5 V Application

### <span id="page-21-0"></span>**LAYOUT AND POWER SUPPLY DECOUPLING CONSIDERATIONS**

When designing with the [AD8141 a](http://www.analog.com/AD8141?doc=AD8141_8142.pdf)n[d AD8142,](http://www.analog.com/AD8142?doc=AD8141_8142.pdf) adhere to standard high speed printed circuit board (PCB) layout practices. A solid ground plane is recommended and good wideband power supply decoupling networks should be placed as close as possible to the supply pins. Small surface-mount ceramic capacitors are recommended for these networks, and tantalum capacitors are recommended for bulk supply decoupling.

### <span id="page-21-1"></span>**AMPLIFIER-TO-AMPLIFIER ISOLATION**

The least amount of isolation between the thre[e AD8142 a](http://www.analog.com/AD8142?doc=AD8141_8142.pdf)mplifiers exists between the green and red channels (Amplifier A and Amplifier B for th[e AD8141\)](http://www.analog.com/AD8141?doc=AD8141_8142.pdf). This is, therefore, viewed as the worst-case isolation, which is reflected in [Table 1 a](#page-2-1)nd the [Theory of Operation](#page-14-0) section.

### <span id="page-21-2"></span>**EXPOSED PADDLE (EPAD)**

The 24-lead LFCSP package has an exposed paddle on the underside of its body. To achieve the specified thermal resistance, it must have a good thermal connection to one of the PCB planes. The exposed paddle must be soldered to a pad on top of the board that is connected with several thermal vias to a ground plane.
