

Low Cost, High Performance Voltage Feedback, 325 MHz Amplifier

AD8057/AD8058

FEATURES

Low cost single (AD8057) and dual (AD8058) High speed 325 MHz, -3 dB bandwidth (G = +1) 1000 V/µs slew rate Gain flatness: 0.1 dB to 28 MHz Low noise 7 nV/ \sqrt{Hz} Low power 5.4 mA/amplifier typical supply current @ 5 V Low distortion -85 dBc @ 5 MHz, R_L = 1 k Ω Wide supply range from 3 V to 12 V Small packaging AD8057 is available in an 8-lead SOIC and 5-lead SOT-23 AD8058 is available in an 8-lead SOIC and an 8-lead MSOP

APPLICATIONS

Imaging DVD/CD Photodiode preamp Analog-to-digital driver Professional cameras filters

GENERAL DESCRIPTION

The AD8057 (single) and AD8058 (dual) are very high performance amplifiers with a very low cost. The balance between cost and performance make them ideal for many applications. The AD8057 and AD8058 reduce the need to qualify a variety of specialty amplifiers. The AD8057 and AD8058 are voltage feedback amplifiers with the bandwidth and slew rate normally found in current feedback amplifiers. The AD8057 and AD8058 are low power amplifiers having low quiescent current and a wide supply range from 3 V to 12 V. They have noise and distortion performance required for high end video systems as well as dc performance parameters rarely found in high speed amplifiers.

The AD8057 and AD8058 are available in standard SOIC packaging as well as tiny 5-lead SOT-23 (AD8057) and 8-lead MSOP (AD8058) packages. These amplifiers are available in the industrial temperature range of -40° C to $+85^{\circ}$ C.

¹ Specification is for device in free air: 8-lead SOIC package: $θ_{JA} = 160^{\circ}C/W$ 5-lead SOT-23-5 package: $θ_{JA} = 240^{\circ}C/W$

8-Lead MSOP package: $\theta_{JA} = 200^{\circ}C/W$

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

MAXIMUM POWER DISSIPATION

The maximum power that can be safely dissipated by the AD8057/AD8058 is limited by the associated rise in junction temperature. Exceeding a junction temperature of 175°C for an extended period can result in device failure. Although the AD8057/AD8058 is internally short-circuit protected, this may not be sufficient to guarantee that the maximum junction temperature (150°C) is not exceeded under all conditions. To ensure proper operation, it is necessary to observe the maximum power derating curves.

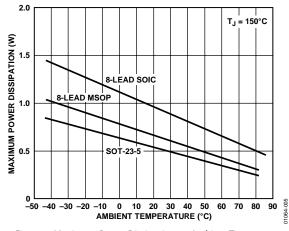

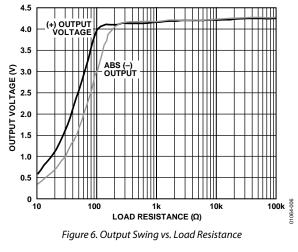

Figure 5. Maximum Power Dissipation vs. Ambient Temperature

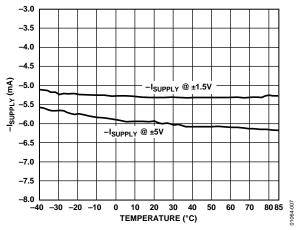

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

TEST CIRCUITS

APPLICATIONS INFORMATION DRIVING CAPACITIVE LOADS

When driving a capacitive load, most op amps exhibit overshoot in their pulse response. Figure 43 shows the relationship between the capacitive load that results in 30% overshoot and the closed-loop gain of an AD8058. It can be seen that, under the gain = +2 condition, the device is stable with capacitive loads of up to 69 pF.

In general, to minimize peaking or to ensure device stability for larger values of capacitive loads, a small series resistor (R_s) can be added between the op amp output and the load capacitor (C_L) as shown in Figure 44.

For the setup shown in Figure 44, the relationship between R_s and C_L was empirically derived and is shown in Table 4.

VIDEO FILTER

Some composite video signals that are derived from a digital source contain some clock feedthrough that can cause problems with downstream circuitry. This clock feedthrough is usually at 27 MHz, which is a standard clock frequency for both NTSC and PAL video systems. A filter that passes the video band and rejects frequencies at 27 MHz can be used to remove these frequencies from the video signal.

Figure 46 shows a circuit that uses an AD8057 to create a single 5 V supply, 3-pole Sallen-Key filter. This circuit uses a single RC pole in front of a standard 2-pole active section. To shift the dc operating point to midsupply, ac coupling is provided by R4, R5, and C4.

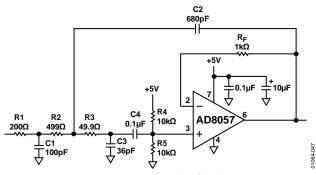

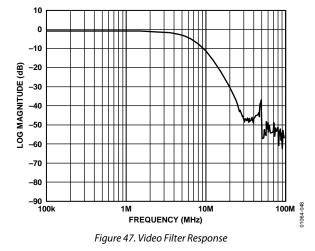

Figure 46. Low-Pass Filter for Video

Figure 47 shows a frequency sweep of this filter. The response is down 3 dB at 5.7 MHz; therefore, it passes the video band with little attenuation. The rejection at 27 MHz is 42 dB, which provides more than a factor of 100 in suppression of the clock components at this frequency.

DIFFERENTIAL ANALOG-TO-DIGITAL DRIVER

As system supply voltages are dropping, many ADCs provide differential analog inputs to increase the dynamic range of the input signal while still operating on a low supply voltage. Differential driving can also reduce second and other evenorder distortion products.

Analog Devices, Inc., offers an assortment of 12- and 14-bit high speed converters that have differential inputs and can be run from a single 5 V supply. These include the AD9220, AD9221, AD9223, AD9224, and AD9225 at 12 bits, and the AD9240, AD9241, and AD9243 at 14 bits. Although these devices can operate over a range of common-mode voltages at their analog inputs, they work best when the common-mode voltage at the input is at the midsupply or 2.5 V.

Op amp architectures that require upwards of 2 V of headroom at the output have significant problems when trying to drive such ADCs while operating with a 5 V positive supply. The low headroom output design of the AD8057 and AD8058 make them ideal for driving these types of ADCs.

The AD8058 can be used to make a dc-coupled, single-endedto-differential driver for one of these ADCs. Figure 48 is a schematic of such a circuit for driving an AD9225, 12-bit, 25 MSPS ADC.

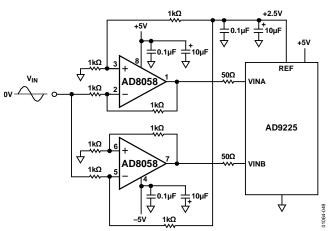

Figure 48. Schematic Circuit for Driving AD9225

In this circuit, one of the op amps is configured in the inverting mode whereas the other is in the noninverting mode. However, to provide better bandwidth matching, each op amp is configured for a noise gain of +2. The inverting op amp is configured for a gain of -1 and the noninverting op amp is configured for a gain of +2. Each of these produces a noise gain of +2, which is determined only by the inverse of the feedback ratio. The input signal to the noninverting op amp is divided by two to normalize its level and make it equal to the inverting output.

For 0 V input, the outputs of the op amps want to be at 2.5 V, which is the midsupply level of the ADCs. This is accomplished by first taking the 2.5 V reference output of the ADC and dividing it by two by a pair of 1 k Ω resistors. The resulting 1.25 V is applied to the positive input of each op amp. This voltage is then multiplied by the gain of +2 of the op amps to provide a 2.5 V level at each output. The assumption for this circuit is that the input signal is bipolar with respect to ground and the circuit must be dc-coupled thereby implying the existence of a negative supply elsewhere in the system. This circuit uses -5 V as the negative supply for the AD8058.

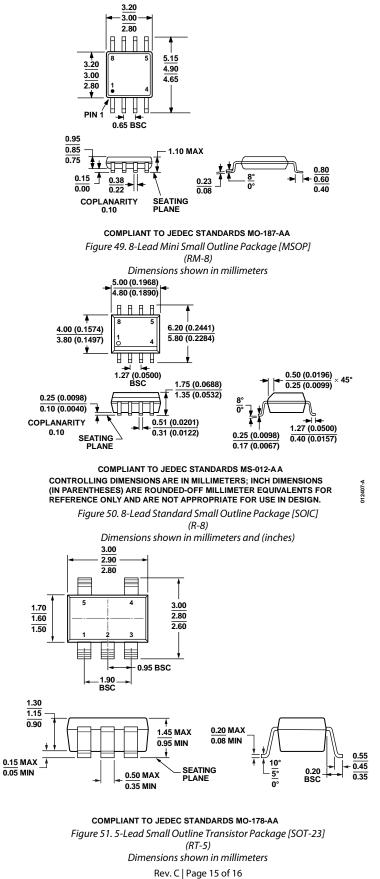

Tying the negative supply of the AD8058 to ground causes a problem at the input of the noninverting op amp. The input common-mode voltage can only go to within 1 V of the negative rail. Because this circuit requires that the positive inputs operate with a 1.25 V bias, there is not enough room to swing this voltage in the negative direction. The inverting stage does not have this problem because its common-mode input voltage remains fixed at 1.25 V. If dc coupling is not required, various ac coupling techniques can be used to eliminate this problem.

LAYOUT

The AD8057 and AD8058 are high speed op amps for use in a board layout that follows standard high speed design rules. Make all signal traces as short and direct as possible. In particular, keep the parasitic capacitance on the inverting input of each device to a minimum to avoid excessive peaking and other undesirable performance. Bypass the power supplies very close to the power pins of the package with a 0.1 μ F capacitor in parallel with a larger (approximately 10 μ F) tantalum capacitor. Connect these capacitors to a ground plane that either is on an inner layer or fills the area of the board that is not used for other signals.
