

Nanopower (900 nA), high accuracy (150  $\mu$ V) 5 V CMOS operational amplifier

## Features

- Sub-micro ampere current consumption:  $I_{CC} = 900$  nA typ. at 25 °C
- Low offset voltage: 150  $\mu$ V max. at 25 °C, 235  $\mu$ V max. over full temperature range (-40 to 85 °C)
- Low noise over 0.1 to 10 Hz bandwidth: 3.6  $\mu$ Vpp
- Low supply voltage: 1.5 V to 5.5 V
- Rail-to-rail input and output
- Gain bandwidth product: 11.5 kHz typ.
- Low input bias current: 10 pA max. at 25 °C
- High tolerance to ESD: 4 kV HBM
- More than 25 years of typical equivalent lifetime supplied by a 220 mA.h CR2032 coin type Lithium battery
- High accuracy without calibration
- Tolerance to power supply transient drops

## Applications

- Gas sensors: CO, O<sub>2</sub>, and H<sub>2</sub>S
- Alarms: PIR sensors
- Signal conditioning for energy harvesting and wearable products
- Ultra long-life battery-powered applications
- Battery current sensing
- Active RFID tags

## Description

The **TSU111**, **TSU112** and the **TSU114** operational amplifiers (op-amp) offer an ultra low-power consumption per channel of 900 nA typical and 1.2  $\mu$ A maximum when supplied by 3.3 V. Combined with a supply voltage range of 1.5 V to 5.5 V, these features allow the TSU11x to be efficiently supplied by a coin type Lithium battery or a regulated voltage in low-power applications.

The high accuracy of 150  $\mu$ V max. and 11.5 kHz gain bandwidth make the TSU11x ideal for sensor signal conditioning, battery supplied, and portable applications.

## 5 Application information

### 5.1 Nanopower applications

The TSU11x can operate from 1.5 V to 5.5 V. The parameters are fully specified at 1.8 V, 3.3 V, and 5 V supply voltages and are very stable in the full  $V_{CC}$  range. Additionally, the main specifications are guaranteed on the industrial temperature range from -40 to 85 °C. The estimated lifetime of the TSU11x exceeds 25 years if supplied by a CR2032 battery (see Figure 34. CR2032 battery).

Figure 34. CR2032 battery

#### 5.1.1 Schematic optimization aiming for nanopower

To benefit from the full performance of the TSU11x, the impedances must be maximized so that current consumption is not lost where it is not required.

For example, an aluminum electrolytic capacitance can have significantly high leakage. This leakage may be greater than the current consumption of the op-amp. For this reason, ceramic type capacitors are preferred.

For the same reason, big resistor values should be used in the feedback loop. However, there are two main limitations to be considered when choosing a resistor.

1. Noise generated: a 100 k $\Omega$  resistor generates 40 nV/ $\sqrt{\text{Hz}}$ , a bigger resistor value generates even more noise.
2. Leakage on the PCB: leakage can be generated by moisture. This can be improved by using a specific coating process on the PCB.

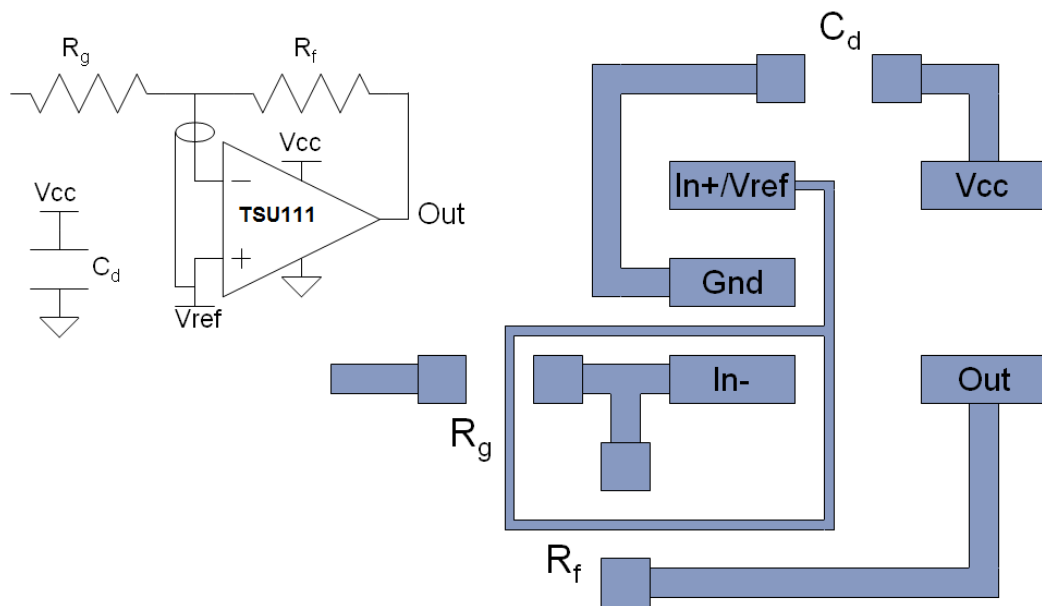

### 5.1.2 PCB layout considerations

For correct operation, it is advised to add 10 nF decoupling capacitors as close as possible to the power supply pins.

Minimizing the leakage from sensitive high impedance nodes on the inputs of the TSU11x can be performed with a guarding technique. The technique consists of surrounding high impedance tracks by a low impedance track (the ring). The ring is at the same electrical potential as the high impedance node.

Therefore, even if some parasitic impedance exists between the tracks, no leakage current can flow through them as they are at the same potential (see [Figure 35. Guarding on the PCB](#)).

**Figure 35. Guarding on the PCB**

### 5.2 Rail-to-rail input

The TSU11x is built with two complementary PMOS and NMOS input differential pairs. Thus, the device has a rail-to-rail input, and the input common mode range is extended from  $(V_{CC-}) - 0.1 \text{ V}$  to  $(V_{CC+}) + 0.1 \text{ V}$ .

The TSU11x has been designed to prevent phase reversal behavior.

### 5.3 Input offset voltage drift overtemperature

The maximum input voltage drift variation overtemperature is defined as the offset variation related to the offset value measured at 25 °C. The operational amplifier is one of the main circuits of the signal conditioning chain, and the amplifier input offset is a major contributor to the chain accuracy. The signal chain accuracy at 25 °C can be compensated during production at application level. The maximum input voltage drift over temperature enables the system designer to anticipate the effect of temperature variations.

The maximum input voltage drift over temperature is computed using [Equation 1](#).

**Equation 1**

$$\frac{\Delta V_{io}}{\Delta T} = \max \left| \frac{V_{io}(T) - V_{io}(25 \text{ °C})}{T - 25 \text{ °C}} \right|$$

Where  $T = -40 \text{ °C}$  and  $85 \text{ °C}$ .

The TSU11x datasheet maximum values are guaranteed by measurements on a representative sample size ensuring a  $C_{pk}$  (process capability index) greater than 1.3.

## 5.4 Long term input offset voltage drift

To evaluate product reliability, two types of stress acceleration are used:

- Voltage acceleration, by changing the applied voltage
- Temperature acceleration, by changing the die temperature (below the maximum junction temperature allowed by the technology) with the ambient temperature.

The voltage acceleration has been defined based on JEDEC results, and is defined using [Equation 2](#).

### Equation 2

$$A_{FV} = e^{\beta \cdot (V_S - V_U)}$$

Where:

$A_{FV}$  is the voltage acceleration factor

$\beta$  is the voltage acceleration constant in 1/V, constant technology parameter ( $\beta = 1$ )

$V_S$  is the stress voltage used for the accelerated test

$V_U$  is the voltage used for the application

The temperature acceleration is driven by the Arrhenius model, and is defined in [Equation 3](#).

### Equation 3

$$A_{FT} = e^{\frac{E_a}{k} \cdot \left( \frac{1}{T_U} - \frac{1}{T_S} \right)}$$

Where:

$A_{FT}$  is the temperature acceleration factor

$E_a$  is the activation energy of the technology based on the failure rate

$k$  is the Boltzmann constant ( $8.6173 \times 10^{-5} \text{ eV.K}^{-1}$ )

$T_U$  is the temperature of the die when  $V_U$  is used ( $^{\circ}\text{K}$ )

$T_S$  is the temperature of the die under temperature stress ( $^{\circ}\text{K}$ )

The final acceleration factor,  $A_F$ , is the multiplication of the voltage acceleration factor and the temperature acceleration factor ([Equation 4](#)).

### Equation 4

$$A_F = A_{FT} \times A_{FV}$$

$A_F$  is calculated using the temperature and voltage defined in the mission profile of the product. The  $A_F$  value can then be used in [Equation 5](#) to calculate the number of months of use equivalent to 1000 hours of reliable stress duration.

### Equation 5

$$\text{Months} = A_F \times 1000 \text{ h} \times 12 \text{ months} / (24 \text{ h} \times 365.25 \text{ days})$$

To evaluate the op amp reliability, a follower stress condition is used where  $V_{CC}$  is defined as a function of the maximum operating voltage and the absolute maximum rating (as recommended by JEDEC rules).

The  $V_{io}$  drift (in  $\mu\text{V}$ ) of the product after 1000 h of stress is tracked with parameters at different measurement conditions (see [Equation 6](#)).

### Equation 6

$$V_{CC} = \max V_{op} \text{ with } V_{icm} = V_{CC} / 2$$

The long term drift parameter ( $\Delta V_{io}$ ), estimating the reliability performance of the product, is obtained using the ratio of the  $V_{io}$  (input offset voltage value) drift over the square root of the calculated number of months ([Equation 7](#)).

### Equation 7

$$\Delta V_{io} = \frac{V_{io} \text{ drift}}{\sqrt{(\text{months})}}$$

Where  $V_{i0}$  drift is the measured drift value in the specified test conditions after 1000 h stress duration.

## 5.5 Using the TSU11x with sensors

The TSU11x has MOS inputs, thus input bias currents can be guaranteed down to 10 pA maximum at ambient temperature. This is an important parameter when the operational amplifier is used in combination with high impedance sensors.

The TSU11x is perfectly suited for trans-impedance configuration. This configuration allows a current to be converted into a voltage value with a gain set by the user. It is an ideal choice for portable electrochemical gas sensing or photo/UV sensing applications. The TSU11x, using trans-impedance configuration, is able to provide a voltage value based on the physical parameter sensed by the sensor.

### 5.5.1 Electrochemical gas sensors

The output current of electrochemical gas sensors is generally in the range of tens of nA to hundreds of  $\mu$ A. As the input bias current of the TSU11x is very low (see [Figure 10](#), [Figure 8](#), [Figure 11](#), [Figure 9](#), and [Figure 12](#), [Figure 10](#)) compared to these current values, the TSU11x is well adapted for use with the electrochemical sensors of two or three electrodes. [Figure 37. Potentiostat schematic using the TSU111](#) shows a potentiostat (electronic hardware required to control a three electrode cell) schematic using the TSU11x. In such a configuration, the devices minimize leakage in the reference electrode compared to the current being measured on the working electrode.

Another great advantage of TSU11x versus the competition is its low noise for low frequencies (3.6  $\mu$ Vpp over 0.1 to 10 Hz), and low input offset voltage of 150  $\mu$ V max. These improved parameters for the same power consumption allow a better accuracy.

**Figure 36. Trans-impedance amplifier schematic**

**Figure 37. Potentiostat schematic using the TSU111**

## 5.6 Fast desaturation

When the TSU11x goes into saturation mode, it takes a short period of time to recover, typically 630  $\mu\text{s}$ . When recovering after saturation, the TSU11x does not exhibit any voltage peaks that could generate issues (such as false alarms) in the application (see [Figure 16](#). [Figure 14](#)).

We can observe that this circuit still exhibits good gain even close to the rails i.e.  $A_{vd}$  greater than 105 dB for  $V_{CC} = 3.3\text{ V}$  with  $V_{out}$  varying from 200 mV up to a supply voltage minus 200 mV. With a trans-impedance schematic, a voltage reference can be used to keep the signal away from the supply rails.

## 5.7 Using the TSU11x in comparator mode

The TSU11x can be used as a comparator. In this case, the output stage of the device always operates in saturation mode. In addition, [Figure 4](#). [Figure 3](#) shows that the current consumption is not higher and even decreases smoothly close to the rails. The TSU11x is obviously an operational amplifier and is therefore optimized for use in linear mode. We recommend using the TS88 series of nanopower comparators if the primary function is to perform a signal comparison only.

## 5.8 ESD structure of the TSU11x

The TSU11x is protected against electrostatic discharge (ESD) with dedicated diodes (see [Figure 38](#). [ESD structure](#)). These diodes must be considered at application level especially when signals applied on the input pins go beyond the power supply rails ( $V_{CC+}$ ) or ( $V_{CC-}$ ).

**Figure 38. ESD structure**

Current through the diodes must be limited to a maximum of 10 mA as stated in [Table 1](#). [Absolute maximum ratings \(AMR\)](#). A serial resistor on the inputs can be used to limit this current.

## 5.9 EMI robustness of nanopower devices

Nanopower devices exhibit higher impedance nodes and consequently they are more sensitive to EMI. To improve the natural robustness of the TSU11x device, we recommend to add three capacitors of around 22 pF each between the two inputs, and between each input and ground. These capacitors lower the impedance of the input at high frequencies and therefore reduce the impact of the radiation.

## 6 Package information

---

In order to meet environmental requirements, ST offers these devices in different grades of **ECOPACK®** packages, depending on their level of environmental compliance. ECOPACK® specifications, grade definitions and product status are available at: [www.st.com](http://www.st.com). ECOPACK® is an ST trademark.

## Revision history

**Table 14. Document revision history**

Date	Revision	Changes
17-Oct-2016	1	Initial release
14-Nov-2016	2	Features: added "rail-to-rail input and output". Description: updated the maximum ultra low-power consumption of TSU111 op-amp. Applications: updated Table 5: added EMIRR typ. values Added Section 5.9: "EMI robustness of nanopower devices".
04-Dec-2017	3	Added the part number TSU112 and the relative package information MiniSO8 and DFN8 2x2.
08-May-2018	4	Updated Section 3 Electrical characteristics.
21-Jan-2019	5	Added the part number TSU114, therefore the document has been updated accordingly.
06-Feb-2019	6	Updated <a href="#">Section 3 Electrical characteristics</a> . Added <a href="#">Figure 5. Input offset voltage vs. input common-mode voltage</a> .
