

### Features

- One full bridge for 6 A load ( $R_{ON} = 150 \text{ m}\Omega$ )
- One half bridges for 3 A load ( $R_{ON} = 300 \text{ m}\Omega$ )
- One configurable high-side driver for up to 1.5 A ( $R_{ON} = 500 \text{ m}\Omega$ ) or 0.35 A ( $R_{ON} = 1600 \text{ m}\Omega$ ) load
- One configurable high-side driver for 0.7 A ( $R_{ON} = 800 \text{ m}\Omega$ ) or 0.35 A ( $R_{ON} = 1600 \text{ m}\Omega$ ) load
- Two high-side drivers for 0.5 A load ( $R_{ON} = 1600 \text{ m}\Omega$ )
- Programmable softstart function to drive loads with higher inrush currents as current limitation value
- Very low  $V_S$  current consumption in standby mode ( $I_S < 6 \mu\text{A typ}$ ;  $T_j \leq 85^\circ\text{C}$ )
- Current monitor output for all high-side drivers
- Central two-stage charge pump
- Motor bridge driver with full  $R_{dson}$  down to 6 V
- Device contains temperature warning and protection
- Open-load detection for all outputs
- Overcurrent protection for all outputs
- Separated half bridges for door lock motor
- Programmable PWM control of all outputs
- STM standard serial peripheral interface (ST-SPI 3.1)
- Prepared for additional fail-safe path for H-bridge

### Applications

- Door actuator driver with 3 bridges for double door lock control, 4 high-side drivers for bulbs and LEDs control.
- H-bridge control for external power transistors

### Description

The L99DZ81EP is a microcontroller driven multifunctional door actuator driver for automotive applications. Up to two DC motors and four grounded resistive loads can be driven with three half bridges and four high-side drivers. Four external MOS transistors in bridge configuration can be driven. The integrated SPI controls all operating modes (forward, reverse, brake and high impedance). Also all diagnostic information is available via SPI read.

# 1 Block diagram and pin description

Figure 1. Block diagram

Table 2. Pin definitions and functions

Pin	Symbol	Function
58	GND <sub>1</sub>	Ground: reference potential. GND1 and GND2 are internally connected. GND2 supplies OUT4-6.
17, 18, 26, 31, 32	GND <sub>2</sub>	Important: For the capability of driving the full current at the outputs, all pins of GND must be externally connected!
17, 57	SGND	Signal Ground: this pin is shared with GND2 pin.

Table 2. Pin definitions and functions (continued)

Pin	Symbol	Function
2, 46, 51, 52	VS <sub>1</sub>	Power supply voltage for power stage outputs (external reverse protection required): for this input a ceramic capacitor as close as possible to GND is recommended. VS1 supplies OUT7-10 and the internal VS supply, VS2 supplies OUT4-6. Important: For the capability of driving the full current at the outputs all pins of VS must be externally connected!
11, 12, 23, 36, 37	VS <sub>2</sub>	
19, 20, 21, 22	OUT4	Half-bridge outputs 4,5,6: the output is built by a high side and a low side switch, which are internally connected. The output stage of both switches is a power DMOS transistor. Each driver has an internal parasitic reverse diode (bulk-drain-diode: high side driver from output to VS, low side driver from GND to output). This output is over current and open load protected.
27, 28, 29, 30	OUT5	
24, 25	OUT6	
40	DO	Serial data output: the diagnosis data is available via the SPI and this 3-state-output. The output remains in 3-state, if the chip is not selected by the input CSN (CSN = high).
34	CM	Current monitor output: depending on the selected multiplexer bits of the Control Register this output sources an image of the instant current through the corresponding high side driver with a fixed ratio.
35	CSN	Chip-Select-Not input: this input is low active and requires CMOS logic levels. The serial data transfer between the device and the micro controller is enabled by pulling the input CSN to low level.
41	DI	Serial data input: the input requires CMOS logic levels and receives serial data from the microcontroller. The data is a 24 bit control word and the most significant bit (MSB, bit 23) is transferred first.
38	CLK	Serial clock input: this input controls the internal shift register of the SPI and requires CMOS logic levels.
33	DIR	Direction Input: this input controls the H-Bridge Drivers.
39	VCC	Supply Voltage: 5 V supply. A ceramic capacitor as close as possible to GND is recommended.
44	OUT9	High-side-driver output 9: the output is built by a high side switch and is intended for resistive loads; hence the internal reverse diode from GND to the output is missing. For ESD reason a diode to GND is present but the energy which can be dissipated is limited. The high-side driver is a power DMOS transistor with an internal parasitic reverse diode from the output to VS (bulk-drain-diode). The output is over current and open load protected.
42	PWMH	PWMH input: this input signal can be used to control the H-Bridge Gate drivers.
3, 43, 45, 48, 49, 50, 53, 54, 55, 56, 59, 60	NC	Not connected.
62, 63	OUT7	High side driver output 8: see OUT9. Important: This output can be configured to supply a bulb with low on-resistance or a LED with higher on-resistance in a different application.
61	OUT8	
47	OUT10	High-side-driver-output 10: see OUT9.

**Table 2. Pin definitions and functions (continued)**

Pin	Symbol	Function
13	GH2	GH2: gate driver for power MOS high side switch in half-bridge 2.
14	SH2	SH2: source of high-side switch in half-bridge 2.
15	GL2	GL2: gate driver for power MOS low side switch in half-bridge 2.
16	SL2	SL2: source of low side switch in half-bridge 2.
64	GH1	GH1: gate driver for power MOS high side switch in half-bridge 1.
1	SH1	SH1: source of high-side switch in half-bridge 1.
4	GL1	GL1: gate driver for power MOS low side switch in half-bridge 1.
5	SL1	SL1: source of low side switch in half-bridge 1.
7	CP1P	CP1P: charge pump pin for capacitor 1, positive side.

## 2 Electrical specifications

### 2.1 Absolute maximum ratings

Stressing the device above the rating listed in [Table 3](#) may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability.

**Table 3. Absolute maximum ratings**

## 3 Application information

### 3.1 Dual power supply: $V_S$ and $V_{CC}$

The power supply voltage  $V_S$  supplies the power drivers and the Power-MOS gate drivers. For supplying the high-side drivers for the power- and gate-driver outputs, an internal charge-pump is used. The SPI interface and the logic circuitry is supplied by  $V_{CC}$ .

Due to the independent  $V_{CC}$  supply the control and status information are not lost, if there are spikes or glitches on the power supply voltage.

### 3.2 Wake up and Active mode/standby mode

After power up of  $V_S$  and  $V_{CC}$  the device operates in standby-mode. Pulling the signal CSN to low level wakes the device up and the analog part is activated (active mode). After at least 10  $\mu$ s, the first SPI communication is valid and the EN-bit can be used to set the EN-mode.

The device can be set into active mode writing a '1' into the EN-register. If the EN-register is not set to '1', the device goes back to standby mode typical 256  $\mu$ s after the rising edge of CSN and all latched data are cleared. In standby mode the current at  $V_S$  ( $V_{CC}$ ) is less than 6  $\mu$ A (5  $\mu$ A) for CSN = high (DO in 3-state). It is recommended to switch all outputs off before entering standby mode.

### 3.3 Charge pump

The charge pump uses two external capacitors, which are switched with a frequency of typically 125 kHz. The output of the charge pump has a current limitation. In standby mode and after a thermal shutdown has been triggered the charge pump is disabled. If the charge pump output voltage remains too low for longer than  $T_{CP}$ , the power-MOS outputs, the EC-control are switched off and the H-Bridge gate drivers are switched to resistive low. The CP\_LOW bit has to be cleared through a software reset to reactivate the drivers.

### 3.4 Diagnostic functions

All diagnostic functions (overcurrent, open-load, power supply overvoltage /undervoltage, temperature warning and thermal shutdown) are internally filtered. The condition has to be valid for at least the associated filter time before the corresponding status bit in the status registers is set. The filters are used to improve the noise immunity of the device. The open-load and temperature warning functions are intended for information purpose and do not change the state of the output drivers. On contrary, the overcurrent condition disables the corresponding driver and thermal shutdown disables all drivers. Without setting the overcurrent recovery bits in the input data register, the microcontroller has to clear the overcurrent status bits to reactivate the corresponding drivers.

### 3.5 Overvoltage and undervoltage detection at $V_S$

If the power supply voltage  $V_S$  rises above the overvoltage threshold  $V_{SOV\_OFF}$ , the outputs OUT4 to OUT10 are switched to high impedance state, the charge pump is disabled and the H-Bridge gate drivers are switched into sink condition to protect the H-bridge and the load. When the voltage  $V_S$  drops below the undervoltage threshold  $V_{SUV\_OFF}$  (UV-switch-OFF voltage), the output stages are switched to high impedance to avoid the operation of the power devices without sufficient gate driving voltage (increased power dissipation). If the supply voltage  $V_S$  recovers to normal operating voltage, the charge pump is switched on again, the CP\_LOW bit is cleared and the output stages return to the programmed state. If the undervoltage/overvoltage recovery disable bit is set, the automatic turn-on of the drivers is deactivated.

If the undervoltage/overvoltage recovery disable bit (OV\_UV\_RD) is set, the microcontroller needs to clear the status bits to reactivate the drivers. It is recommended to set OV\_UV\_RD bit to avoid a possible high current oscillation in case of a shorted output to GND and low battery voltage.

### 3.6 Overvoltage and undervoltage detection at $V_{CC}$

At power-on ( $V_{CC}$  increases from undervoltage to  $V_{POROFF}$ ) the circuit is initialized by an internally generated power-on-reset (POR). If the voltage  $V_{CC}$  decreases below the low threshold ( $V_{PORON}$ ), the outputs are switched to 3-state (high impedance) and the status registers are cleared. If the voltage at pin  $V_{CC}$  increases above the  $V_{CC}$  reset high threshold  $V_{VCCRESHU}$ , the device enters the reset state, all outputs are switched off and all internal registers are cleared. After the voltage at pin  $V_{CC}$  has decreased below  $V_{VCCRESHL}$ , the device enters normal operating mode again and the internal registers are reset.

### 3.7 Temperature warning and shutdown

If the junction temperature rises above the temperature warning threshold ( $T_{jTW}$ ), a temperature warning flag is set after the temperature warning filter time ( $T_{jff}$ ) and can be read via SPI. If the junction temperature increases above the temperature shutdown threshold ( $T_{jTS}$ ), the thermal shutdown bit is set and the power transistors of all output stages are switched off to protect the device after the thermal shutdown filter time. The gates of the H-Bridge are discharged by the 'Resistive Low' mode.

The temperature warning and thermal shutdown flags are latched and must be cleared by the microcontroller. This is done by a read and clear command on an arbitrary register, because both bits are part of the global status register.

After these bits have been cleared, the output stages are reactivated. If the temperature is still above the thermal warning threshold, the thermal warning bit is set after  $T_{jff}$ . Once this bit is set and the temperature is above the temperature shutdown threshold, temperature shutdown is detected after  $T_{jff}$  and the outputs are switched off. Therefore the minimum time after which the outputs are switched off after the bits have been cleared in case the temperature is still above the thermo-shutdown threshold is twice the thermo-warning/-shutdown filter time  $T_{jff}$ .

### 3.8 Inductive loads

Each half bridge is built by internally connected high- and low-side power DMOS transistors. Due to the built-in reverse diodes of the output transistors, inductive loads can be driven at the outputs OUT4 to OUT6 without external freewheeling diodes. The high-side drivers OUT7 to OUT10 are intended to drive resistive loads. Therefore only a limited energy ( $E < 1 \text{ mJ}$ ) can be dissipated by the internal ESD-diodes in freewheeling condition. For inductive loads ( $L > 100 \mu\text{H}$ ) an external freewheeling diode connected between GND and the corresponding output is required.

### 3.9 Open-load detection

The open load detection monitors the load current in each activated output stage. If the load current is below the open load detection threshold for at least  $t_{\text{FOL}}$  the corresponding open-load bit is set in the status register. Due to mechanical/electrical inertia of typical loads a short activation of the outputs (e.g. 3 ms) can be used to test the open load status without changing the mechanical/electrical state of the loads.

### 3.10 Overcurrent detection

In case of an overcurrent condition, a flag is set in the status register. If the overcurrent signal is valid for at least  $T_{\text{FOC}}$ , the overcurrent flag is set and the corresponding driver is switched off to reduce the power dissipation and to protect the integrated circuit. If the overcurrent recovery bit of the output is cleared, the microcontroller has to clear the status bits to reactivate the corresponding driver.

### 3.11 Current monitor

The current monitor output sources a current image at the current monitor output, which has three fixed ratios of the instantaneous current of the selected high-side driver. Outputs with a resistance of  $500 \text{ m}\Omega$  and higher have a ratio of  $1/2000$ , except for OUT8, which has a ratio of  $1/6500$ , and those with a lower resistance one of  $1/10000$ . The signal at output CM is blanked after switching on the driver until correct settlement of the circuitry. The bits  $\text{CM\_SEL}_{<3:0>}$  define which of the outputs are multiplexed to the current monitor output CM. The current monitor output allows a more precise analysis of the actual state of the load rather than the detection of an open- or overload condition. For example, it can be used to detect the motor state (starting, free running, stalled). Moreover, it is possible to control the power of the defroster more precisely by measuring the load current. The current monitor output is enabled after the current-monitor blanking time, when the selected output is switched on. If this output is off, the current monitor output is in high-impedance mode.

### 3.12 PWM mode of the power outputs

Each driver has a corresponding PWM enable bit, which can be programmed by the SPI interface. If the PWM enable bit is set, the output is controlled by the logically AND-combination of an internally generated PWM signal and the output control bit of the corresponding driver. The PWM-Frequency of all outputs can be programmed to either 122 Hz or 244 Hz typically. The on-duty-cycle is set by the four 7-bit registers, which control one PWM counter each. Therefore the maximum on-time is  $100\% - 1 \text{ LSB}$ .

1 LSB = 100/128 %. Which output uses which corresponding PWM driver can be seen in the SPI register definition. When programming a specific duty-cycle, the output on/off times as well as the slopes must be taken into account.

### 3.13 Cross-current protection

The six half-bridges of the device are crosscurrent protected by an internal delay time. If one driver (LS or HS) is turned off, the activation of the other driver of the same half bridge is automatically delayed by the crosscurrent protection time. After the crosscurrent protection time is expired the slew-rate limited switch-off phase of the driver is changed to a fast turn-off phase and the opposite driver is turned-on with slew-rate limitation. Due to this behavior, it is always guaranteed that the previously activated driver is completely turned off before the opposite driver starts to conduct

### 3.14 Programmable soft-start function to drive loads with higher inrush current

Loads with start-up currents higher than the overcurrent limits (e.g. inrush current of lamps, Start current of motors and cold resistance of heaters) can be driven by using the programmable softstart function (i.e. overcurrent recovery mode). Each driver has a corresponding overcurrent recovery bit. If this bit is set, the device automatically switches the outputs on again after a programmable recovery time. The duty cycle in overcurrent condition can be programmed by the SPI interface to about 12 % or 25 %. The PWM modulated current provides sufficient average current to power up the load (e.g. heat up the bulb) until the load reaches operating condition. The PWM frequency settles at 1.7 kHz and 3 kHz. The device itself cannot distinguish between a real overload and a non linear load like a light bulb. A real overload condition can only be qualified by time. For overload detection the microcontroller can switch on the light bulbs by setting the overcurrent recovery bit for the first e.g. 50 ms. After clearing the recovery bit the output is automatically switched off, if the overload condition remains. This overcurrent detection procedure has to be followed in order to make it possible to switch on the low side driver of a bridge output, if the associated high-side driver has been used in recovery mode before.

Figure 13. Overcurrent recovery mode

### 3.15 H-bridge control (DIR, PWMH, bits SD, SDS)

The PWMH input controls the drivers of the external H-bridge transistors. The motor direction can be chosen with the direction input (DIR), the duty cycle and frequency with the PWMH input. With the SPI-registers SD and SDS four different slow-decay modes (via drivers and via diode) can be selected using the high side or the low side transistors. Unconnected inputs are defined by internal pull-down current.

1. Only the half-bridge (low and high-side), in which one MOSFET is in short circuit condition is switched off. Both MOSFETs of the other half-bridge remain active and driven by DIR and PWMH

### 3.16 H-bridge driver slew-rate control

The rising and falling slope of the drivers for the external high-side Power-MOS can be slew rate controlled. If this mode is enabled the gate of the external high-side Power-MOS is driven by a current source instead of a low-impedance output driver switch as long as the drain-source voltage over this Power-MOS is below the switch threshold. The current is programmed using the bits SLEW<4:0>, which represent a binary number. This number is multiplied by the minimum current step. This minimum current step is the maximum source-/sink-current ( $I_{GHx_{rmax}} / I_{GHx_{fmax}}$ ) divided by 31. Programming SLEW<4:0> to 0 disables the slew rate control and the output is driven by the low-impedance output driver switch.

Figure 14. H-bridge GSHx slope

### 3.17 Resistive low

The resistive output mode protects the L99DZ81EP and the H-bridge in the standby mode and in some failure modes (thermal shut down (TSD), charge pump low (CP\_LOW) and stuck-at-'1' at pin DI). When a gate driver changes into the resistive output mode due to a failure a sequence is started. In this sequence the concerning driver is switched into sink condition for 32  $\mu$ s to 64  $\mu$ s to ensure a fast switch-off of the H-bridge transistor. If slew rate control is enabled, the sink condition is slew-rate controlled. Afterwards the driver is switched into the resistive output mode (resistive path to source).

### 3.18 Short circuit detection/drain source monitoring

The drain source voltage of each activated external MOSFET of the H-bridge is monitored by comparators to detect shorts to ground or battery. If the voltage-drop over the external MOSFET exceeds the threshold voltage  $V_{SCd}$  for longer than the short current detection time  $t_{SCd}$  the corresponding gate driver switches the external MOSFET off and the corresponding drain source monitoring flag (DS\_MON[3:0]) is set. The DS\_MON bits have

to be cleared through the SPI to reactivate the gate drivers. The drain source monitoring has a filter time of typ. 6  $\mu$ s. This monitoring is only active while the corresponding gate driver is activated. If a drain-source monitor event is detected, the corresponding gate-driver remains activated for at maximum the filter time. When the gate driver switches on, the drain-source comparator requires the specified settling time until the drain-source monitoring is valid. During this time, this drain-source monitor event may start the filter time. The threshold voltage  $V_{SCd}$  can be programmed using the SPI.

**Table 25. H-bridge DS-monitor threshold**

DIAG<1>	DIAG<0>	Monitoring threshold voltage (typical)
0	0	$V_{SCD1} = 0.5\text{ V}$
0	1	$V_{SCD2} = 1.0\text{ V}$
1	0	$V_{SCD3} = 1.5\text{ V}$
1	1	$V_{SCD4} = 2.0\text{ V}$

**Figure 15. H-bridge diagnosis**

### 3.19 H-bridge monitoring in off-mode

The drain source voltages of the H-Bridge driver external transistors can be monitored, while the transistors are switched off. If either bit OL\_H1L2 or OL\_H2L1 is set to '1', while bit HEN = '1', the H-drivers enter resistive low mode and the drain-source voltages can be monitored. Since the pull-up resistance is equal to the pull-down resistance on both sides of

the bridge a voltage of  $2/3 V_S$  on the pull-up high-side and  $1/3 V_S$  on the low side is expected, if they drive a low-resistive inductive load (e.g. motor). If the drain source voltage on each of these Power-MOS is less than  $1/6 V_S$ , the drain-source monitor bit of the associated driver is set.

In case of a short to ground the drain-source monitor bits of both low-side gate drivers are set. A short to  $V_S$  can be diagnosed by setting the “H-Bridge OL high threshold (H-OLTH HIGH)” bit to one.

### 3.20 Programmable cross current protection

Both external MOSFET transistors in one half-bridge are disabled for the cross-current protection time ( $t_{CCP}$ ) after one MOSFET inside this halfbridge is switched off to prevent current flowing from the high-side to the low-side MOSFET.

The cross current protection time  $t_{CCP}$  can be programmed by SPI using bits COPT<3:0>.

### 3.21 Watchdog

The watchdog monitors the  $\mu\text{C}$  during normal operation within a nominal trigger cycle of 60ms. The watchdog is triggered by toggling the watchdog bit, which restarts the watchdog timer (i.e. content of the watchdog trigger bit has to be inverted). If no watchdog bit inversion has been occurred during the watchdog time-out time  $T_{\text{WDTO}}$  the H-bridge drivers switch into resistive-low condition, all power outputs are switched off.

## 4 Functional description of the SPI

### 4.1 General description

The SPI complies with Standard ST-SPI Interface Version 3.1.

Its communication is based on a Serial Peripheral Interface structure using CSN (Chip Select Not), DI (Serial Data In), DO (Serial Data Out/Error) and CLK (Serial Clock) signal lines.

#### 4.1.1 Chip Select Not (CSN)

The CSN input pin is used to select the serial interface of this device. When CSN is high, the output pin (DO) is in high impedance state. A low signal wakes up the device and a serial communication can be started. The state when CSN is going low until the rising edge of CSN is called a communication frame.

#### 4.1.2 Serial Data In (DI)

The DI input pin is used to transfer data serially into the device. The data applied to the DI is sampled at the rising edge of the CLK signal. A stuck-at '0' or '1' enters the standby mode.

#### 4.1.3 Serial Clock (CLK)

The CLK input signal provides the timing of the serial interface. The Data Input (DI) is latched at the rising edge of Serial Clock CLK. The SPI can be driven by a micro controller with its SPI peripheral running in following mode: CPOL = 0 and CPHA = 0. Data on Serial Data Out (DO) is shifted out at the falling edge of the serial clock (CLK). The serial clock CLK must be active only during a frame (CSN low). Any other switching of CLK close to any CSN edge could generate set up/hold violations in the SPI logic of the device. The clock monitor counts the number of clock pulses during a communication frame (while CSN is low). If the number of CLK pulses does not correspond to the frame width indicated in the <SPI-frame-ID> (ROM address 03H) the frame is ignored and the <frame error> bit in the <Global Status Byte> is set.

*Note: Due to this safety functionality, daisy chaining the SPI is not possible. Instead, a parallel operation of the SPI bus by controlling the CSN signal of the connected ICs is recommended.*

#### 4.1.4 Serial Data Out (DO)

The data output driver is activated by a logical low level at the CSN input and goes from high impedance to a low or high level depending on the global status bit 7 (Global Error Flag). The content of the selected status or control register is transferred into the data out shift register after the address bits have been transmitted. Each subsequent falling edge of the CLK shifts the next bit out.

#### 4.1.5 SPI communication flow

At the beginning of each communication the master can read the contents of the <SPIframe-ID> register (ROM address 03H) of the slave device.

This 8-bit register indicates the SPI frame length (24 bit) and the availability of additional features. Each communication frame consists of a command byte, which is followed by two data bytes.

The data returned on DO within the same frame always starts with the <Global Status> Byte. It provides general status information about the device. It is followed by two data bytes (i. e. 'In-frame-response').

For write cycles the <Global Status> Byte is followed by the previous content of the addressed register.

OCx: operation code

Ax: address

Dx: data bit

Each communication frame starts with a command byte. It consists of an operating code which specifies the type of operation (<Read>, <Write>, <Read and Clear>, <Read Device Information>) and a 6 bit address. If less than 6 bits are required, the remaining bits are unused but are reserved.

### 4.2.1 Operation code definition

OC1	OC0	Meaning
0	0	<Write Mode>
0	1	<Read Mode>
1	0	<Read and Clear Mode>
1	1	<Read Device Information>

The <Write Mode> and <Read Mode> operations allow access to the RAM of the device.

A <Read and Clear Mode> operation is used to read a status register and subsequently clear its content.

The <Read Device Information> allows access to the ROM area which contains device related information such as <ID-Header>, <Product Code>, <Silicon Version> and <SPI-frame-ID>.

## 5 SPI - control and status registers

Table 31. Global status byte

Bit	7	6	5	4	3	2	1	0
Name	GL_ER	CO_ER	C_RESET	TSD	TW	UOV_OC_DS	OL	NR
Reset	0	0	1	0	0	0	0	0

- GL\_ER:** Global Error Flag.  
Failures of bits 6 to 0 are always linked to the Global Error Flag. This flag is set, if at least one of these bits indicates a failure. It is reflected via the DO pin while CSN is held low and no SPI clock signal is applied. This operation does not cause the Communication Error bit in the <Global Status> to be set. The signal TW bit3 and OL bit1 can be masked.
- CO\_ER:** Communication Error.  
If the number of clock pulses during the previous frame is not 24, the frame is ignored and this bit is set.
- C\_RESET:** Chip RESET.  
If a stuck at '1' on input DI during any SPI frame occurs, or if a Power On Reset (VCC monitor) occurs. C\_RESET is reset ('1') with any SPI command. When C\_RESET is active ('0'), the gate drivers are switched off (resistive path to source). After a startup of the circuit C\_RESET is active due to the power-up reset pulse. Therefore, the gate drivers are switched off. They can only be activated after the C\_RESET has been reset by an SPI command.
- TSD:** Thermal shutdown.  
All gate drivers and the charge pump are switched off (resistive path to source). The TSD bit has to be cleared through a read and clear command to reactivate the gate drivers and the chargepump.
- TW:** Thermal Warning.  
This bit can be masked using the configuration register.
- UOV\_OC\_DS:** Logical OR of the filtered undervoltage/overvoltage, chargepump-low, overcurrent of the power outputs and the H-bridge drain-source monitor signals.
- OL:** Open-load.  
Logical OR of the filtered output driver open-load signals. This bit can be masked using the configuration register.
- NR:** Not Ready.  
After switching the device from standby mode to active mode an internal timer is started to allow the chargepump to settle before the outputs can be activated. This bit is cleared automatically after the startup time.

## 5.1 Control Register 0

Table 32. Control Register 0

Bit	Name	Access	Reset	Content
15	0	—	0	Reserved (must be set to '0')
14	0	—	0	
13	0	—	0	
12	0	—	0	
11	0	—	0	
10	0	—	0	
9	OUT4_HS on/off	Read/write	0	The corresponding output driver is activated, if this bit is set. Setting the PWM enable bit, the driver is only switched on, if the PWM timer enables it. An internal cross-current protection prevents, that both the low- and high-side of the half-bridges OUT4-OUT6 are switched on simultaneously.
8	OUT4_LS on/off	Read/write	0	
7	OUT5_HS on/off	Read/write	0	
6	OUT5_LS on/off	Read/write	0	
5	OUT6_HS on/off	Read/write	0	
4	OUT6_LS on/off	Read/write	0	
3	0	—	0	Reserved (must be set to '0')
2	0	—	0	
1	0	—	0	
0	EN	Read/write	0	The device is switched into active mode, if EN is '1'. It enters the standby mode, if the EN bit is '0'. In standby mode all bits are reset.

## 6 Package and packing information

### 6.1 ECOPACK<sup>®</sup> package

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK<sup>®</sup> packages, depending on their level of environmental compliance. ECOPACK<sup>®</sup> specifications, grade definitions and product status are available at: [www.st.com](http://www.st.com). ECOPACK<sup>®</sup> is an ST trademark.
