

# **Non-Dimmable, Off-Line, LED Driver with Low Total Harmonic Distortions**

# **Features**

- Good LED Current Regulation
	- Better than 5% accuracy
- Valley Switching Buck-Boost Converter with Power Factor Correction (PFC)
	- 0.97 Power Factor (typical)
	- 5% Total Harmonic Distortion (THD) (typical)
- Uses a Standard Off-the-Shelf Inductor - No auxiliary winding required
- Single Input Voltage Range
	- HV98100: 110 V<sub>AC</sub> ±15%
	- HV98101: 230 V<sub>AC</sub> ±15%
- Supports 5W-15W Output Power
- Space-saving SOT-23-6L Package

# **Applications**

- LED Lamps
- LED Lighting Fixtures

# **Description**

The HV98100/HV98101 LED driver integrated circuit (IC) is an off-line, high-power factor, buck-boost controller targeted at general LED lighting products, such as LED lamps and LED lighting fixtures with a maximum power rating of about 15W.

Valley-switching buck-boost converters are preferred in off-line applications since they reduce switching losses. A typical solution is to pair a constant on-time control scheme with valley switching to achieve both a high-power factor and good efficiency. However, this control scheme results in a higher total harmonic distortion, and the actual value is dependent on the input and output voltages. The HV98100/HV98101 uses a unique control scheme to achieve a high-power factor and low THD simultaneously under all line and load conditions, while maximizing efficiency utilizing valley switching. The average LED current is also controlled in a closedloop manner to achieve high LED accuracy.

Other unique features of the ICs are the bootstrap of the IC supply voltage from the output, as well as the unique valley-sensing scheme that allows the use of a standard off-the-shelf inductor to minimize the overall system cost.

Applications with low-output voltage can be accommodated using a coupled inductor.

# **3.0 PIN DESCRIPTION**

The description of the pins are listed in [Table](#page-6-0) 3-1.

## <span id="page-6-0"></span>**TABLE 3-1: PIN DESCRIPTION**

## **3.1 IND**

This pin is used for detecting the valley, as well as for over-voltage protection. The voltage at pin is maintained at approximately 4.3V. When the switching FET is off, current is sourced out of this pin. If this current exceeds 450 μA, then over voltage is detected and the IC shuts down. This current sourced out of the pin is also used to detect the valley, using a patented method.

For proper operation, the IND pin should be shielded to prevent mis-triggering due to the large voltage slew rates present in application. A recommended layout is shown in [Figure](#page-6-1) 3-1.

<span id="page-6-1"></span>

# **3.2 Power Ground Pin (GND)**

This is the ground pin of the IC. The  $V_{DD}$  capacitor and COMP network should be connected to this pin and the GND pin should be connected to the sense resistor, as shown in the [Typical Application Circuit](#page-1-0) for proper functioning of the IC. [Figure](#page-6-2) 3-2 shows a recommended layout. Red traces in the layout are on the top layer, whereas blue traces on the layout are on the bottom layer.

<span id="page-6-2"></span>*FIGURE 3-2: Connection to the GND Pin.*

# **3.3 COMP**

This pin is the output of the internal transconductance amplifier. A compensation network connected between COMP and GND pins is used to stabilize the closed loop control of the LED current.

# **3.4 CS**

This pin is used to sense the inductor current. The inductor current information is used to derive the output LED current, as well as to protect the inductor from saturation.

# 3.5 PV<sub>DD</sub>

This pin is the power supply pin for the IC. A minimum of 4.7 μF capacitor needs to be connected between  $PV<sub>DD</sub>$  and GND for stability of the internal shunt regulator. The  $C_{\text{PVDD}}$  capacitor needs to be placed physically close to the IC to minimize the trace length between the  $PV<sub>DD</sub>$  pin and the capacitor.

# **3.6 GATE**

This pin is the gate drive output of the IC and is used to control the switching of the external FET.

# **4.0 FUNCTIONAL DESCRIPTION**

# **4.1 Introduction**

The HV98100/HV98101 control ICs provide constant average LED current for LED lamps and fixtures with a single-stage, valley-switching, buck-boost powersupply topology.

The IC is targeted at designs at a single-line voltage, such as 110  $V_{AC}$  (HV98100) or 230  $V_{AC}$  (HV98101) and does not support designs for universal input voltage range.

# **4.2 Principle of Operation**

The IC adopts a novel control mechanism to vary both on-time and switching period at the same instant over the line cycle in a way that forces the average input current to be proportional to the input voltage, realizing high-power factor and low THD which is independent of the load voltage  $(V<sub>O</sub>)$  (unlike a constant on-time control where the THD is dependent on the LED string voltage).

In order to determine the LED current regulation, power balancing is used to maintain the mean programmable LED current  $(I<sub>O</sub>)$  in a closed-loop manner by means of the adaptive  $V_{\text{COMP}}$  swing upon the defined input/output voltage variation, as shown in [Equation](#page-8-0) 4-1.

# <span id="page-8-0"></span>**EQUATION 4-1:**

$$
I_{O} = \frac{V_{in,rms}^{2} \cdot K_{T} \cdot V_{COMP}}{V_{O}}
$$

Assume a  $V_{\text{COMP}}$  variation from 1.2V to 3.8V, an input voltage ( $V_{IN,rms}$ ) variation of ±15% and the internal timing constant  $(K_T)$  variation of ±12%. With these assumptions, the maximum variation in the LED string voltage (to maintain constant LED current) cannot exceed ±18% approximately.

# **5.0 APPLICATION INFORMATION**

# **5.1 Introduction**

This section describes the operation of the various blocks in the IC. Detailed design information, along with a design example, is provided in **Section [6.0 "Design](#page-11-0)  [Example"](#page-11-0)**.

# 5.2 PV<sub>DD</sub> Regulator

The supply current is initially fed from the rectified AC input directly via an external start-up resistor  $(R_{HV})$  to peak charge a hold-up capacitor  $(C_{PVDD})$  connected at this pin. Note that a switching diode  $(D_{HV})$  is required in series to prevent the capacitor from discharging when the buck-boost converter FET  $(M_{BBT})$  turns on. As the voltage on the  $V_{DD}$  capacitor increases, the IC is held in a Stand-by mode and draws minimum current (200  $\mu$ A max.). Once the voltage at  $V_{DD}$  reaches  $V_{DD,ON}$ , the IC turns on and starts switching at an internally fixed switching frequency of 10 kHz, until the valley can be detected. Once the valley is detected, the converter starts working in the normal Valley-Switching mode and tries to regulate the LED current. In this mode, the current drawn by the IC from  $V_{DD}$  increases causing the voltage across the  $V_{DD}$  capacitor to start dropping (since the current supplied by the external start-up resistor is not sufficient).

If the  $V_{DD}$  voltage drops below  $V_{DD,OFF}$ , the IC enters into Stand-by mode and the process starts again. If the bootstrap from the output capacitor  $(C<sub>O</sub>)$  is available to prevent the  $V_{DD}$  voltage from going below  $V_{DD,DEF}$ , then the LED driver operates normally. In this way, as shown in [Figure](#page-9-0) 5-1, the  $PV_{DD}$  voltage bounces between  $V_{DD,ON}$  and  $V_{DD,OFF}$  within a hysteresis band for the IC to start GATE switching, until the energy stored in the output capacitor can be partially delivered to  $PV<sub>DD</sub>$  through the bootstrapping resistor-diode network (R<sub>PVDD</sub>-D<sub>PVDD</sub>).

<span id="page-9-0"></span>*FIGURE 5-1: Typical Startup Waveforms.*

The IC includes an internal  $V_{DD}$  clamp circuit. The clamp limits the voltage on the  $V_{DD}$  supply pin to the maximum value ( $PV_{DD,clamp}$ ). If the maximum current supplied through the external resistors minus the current consumption of the IC is lower than the maximum value that the Zener clamp can sustain  $(I_{DD,MAX})$ , no external Zener diode is required.

# **5.3 LED Current Regulator**

The LED current  $(I<sub>O</sub>)$  is sensed directly using an external sense resistor  $R_{CS}$  and compared to an internal fixed reference  $(CS_{REF}$ ). An internal transconductance amplifier is used to close the loop on the LED current with an external compensation capacitor. The LED current can be programmed as in [Equation](#page-9-1) 5-1.

#### <span id="page-9-1"></span>**EQUATION 5-1:**

$$
I_{LED} = \frac{CS_{REF}}{R_{CS}}
$$

## **5.4 Valley Switching**

The driver incorporates valley switching (quasi-resonant switching), a technique for reducing switching loss at the turn-on event of the buck-boost converter FET. Valley detect is accomplished by sensing the current sunk into the IND pin when the GATE is low. The operation is illustrated in [Figure](#page-9-2) 5-2. When the inductor current  $I_1$  has decreased to zero at  $t_2$ , the positive LED voltage  $V_1$  starts to oscillate around the 0V level (with respect to the IC GND), with an amplitude  $V<sub>O</sub>$ . The GATE turns on again when the first lowest level (valley) is detected.

<span id="page-9-2"></span>*FIGURE 5-2: Valley Detect Waveforms.*

However, in case the valley is not detected (during startup, output short circuit and input voltage zero crossings), a 10 kHz internal clock is used to start the next cycle.

# **5.5 Over-Voltage and Short-Circuit Protection**

# 5.5.1 OVER-VOLTAGE PROTECTION

Apart from the valley detect, measuring the current sunk into the IND pin when the GATE is low can be used to sense an output over voltage or open circuit. The IND triggering level is  $I_{\text{OVP}}$ .

When the current into the IND pin exceeds  $I_{\text{OVP}}$ , the gate driver shuts down. The PV<sub>DD</sub> capacitor starts discharging (since there is no bootstrap and the current through the input start-up resistor is insufficient to charge the capacitor). Once the voltage at  $PV<sub>DD</sub>$  drops to  $V_{DD,OFF}$ , the IC goes into a low-current mode and the start-up procedure starts. This process keeps repeating until the over-voltage condition disappears.

#### 5.5.2 SHORT-CIRCUIT PROTECTION

Output short circuit (or input under voltage) causes the converter to go into Continuous Conduction mode (CCM) by sensing the inductor current when  $M<sub>BBT</sub>$  is on.

When the GATE turns on, a leading edge blanking circuit is activated within the IC. The blanking circuit has two functions:

- 1. Blank the first T<sub>BLNKOCP</sub> of the GATE on-time. During this time,  $R_{CS}$  will detect the leading edge spike, and the edge spike is not allowed to propagate to the comparator since it might cause false triggering of the OCP comparator.
- 2. Allow the OCP comparator to see the next T<sub>DETOCP</sub> of the inductor current. Since the converter is assumed to be in Boundary Conduction mode during normal operation, when the GATE turns on, the inductor current will start at zero and start ramping up. The IC compares the second voltage across  $R_{CS}$  in the detect window after the GATE turns on and determines if the converter is operating in CCM.

If the IC detects four consecutive cycles of CCM, the GATE is turned off and the IC goes through a POR.

Typical waveforms are shown in [Figures](#page-10-0) 5-3 and [5-4.](#page-10-1)

<span id="page-10-0"></span>*FIGURE 5-3: Waveforms During Normal Operation.*

<span id="page-10-1"></span>

# <span id="page-11-0"></span>**6.0 DESIGN EXAMPLE**

This section describes the procedure to design an HV98100/HV98101 LED driver. The specifications used for this example are:

- **Input:** 230  $V_{AC}$  r.m.s  $\pm$ 15%, 50 Hz
- **Output Current:** 150 mA
- **LED String Voltage:** 88V 122V

# **6.1 Power stage design**

#### 6.1.1 CALCULATING INPUT CURRENT

The maximum output power  $(P_{Omax})$  can be computed as:

## **EQUATION 6-1:**

$$
P_{O, max} = V_{O, max} \cdot I_{O} = 122V \cdot 150 \text{ mA} = 18.3W
$$

Assuming a sinusoidal input current wave-shape, the peak input current at the minimum input voltage and maximum output power can be computed to be:

#### <span id="page-11-1"></span>**EQUATION 6-2:**

$$
I_{IN, max, pk} = \frac{\sqrt{2} \cdot P_{O, max}}{V_{IN, min, rms} \cdot \eta} = \frac{\sqrt{2} \cdot 18.3 W}{195.5 V \cdot 0.85} = 156 mA
$$
  
where:  
 $\eta$  = the assumed efficiency of the converter

## 6.1.2 SELECTING THE INDUCTOR

The typical inductor current waveform for a Boundary Conduction mode buck-boost converter is shown in [Figure](#page-9-2) 5-2. Ignoring the dead-time, the peak input current can be expressed as a function of the peak inductor current.

## <span id="page-11-2"></span>**EQUATION 6-3:**

$$
I_{IN, max, peak} = \frac{1}{2} \cdot I_{L, max, pk} \cdot \frac{T_{ON, max}}{T_{S, max}}
$$

Since a Boundary Conduction mode converter has the same DC transfer function as a Continuous Conduction mode (CCM) converter, the ratio of the on-time to the switching frequency can be expressed as:

#### <span id="page-11-3"></span>**EQUATION 6-4:**

$$
\frac{T_{ON,max}}{T_{S,max}} = \frac{1}{1 + \frac{\sqrt{2} \cdot V_{IN,min,rms}}{V_{O,max}}} = \frac{1}{1 + \frac{\sqrt{2} \cdot 195.5V}{122V}} = 0.31
$$

Combining [Equations](#page-11-1) 6-2, [6-3](#page-11-2) and [6-4](#page-11-3):

#### <span id="page-11-4"></span>**EQUATION 6-5:**

$$
I_{L,max, pk} = 2 \cdot I_{IN,max, peak} \cdot \frac{T_{S,max}}{T_{ON,max}}
$$

$$
= 2 \cdot 156 \text{ mA} \cdot \frac{1}{0.31} = 1 \text{ A}
$$

Assuming a minimum switching frequency of 30 kHz, the inductor value can be computed as:

#### **EQUATION 6-6:**

$$
T_{ON,max} = \frac{T_{S,max}}{I + \frac{\sqrt{2} \cdot V_{IN,min,rms}}{V_{O,max}}} = \frac{33.33 \text{ }\mu\text{s}}{I + \frac{\sqrt{2} \cdot 195.5 \text{ V}}{122 \text{ V}}} = 10.2 \text{ }\mu\text{s}
$$

## **EQUATION 6-7:**

$$
L_{BBT} = \frac{\sqrt{2} \cdot V_{IN,min,rms} \cdot T_{ON,max}}{I_{L,max,pk}}
$$

$$
= \frac{\sqrt{2} \cdot 195.5V \cdot 10.2 \text{ }\mu\text{s}}{I A} = 2.79 \text{ }mH
$$

The inductor peak current has already been computed in [Equation](#page-11-4) 6-5. The r.m.s current can be computed using:

#### **EQUATION 6-8:**

$$
K_{IL} = \sqrt{\frac{(\sqrt{2} \cdot V_{IN,min,rms})^{2}}{8 \cdot V_{O,max}^{2}} + \frac{8 \cdot \sqrt{2} \cdot V_{IN,min,rms}}{9 \cdot \pi \cdot V_{O,max}} + \frac{1}{6}}
$$
  
=  $\sqrt{\frac{(\sqrt{2} \cdot 195.5V)^{2}}{8 \cdot 122V^{2}} + \frac{8 \cdot \sqrt{2} \cdot 195.5V}{9 \cdot \pi \cdot 122V} + \frac{1}{6}}$   
= 1.204

#### **EQUATION 6-9:**

$$
I_{L,rms} = K_{IL} \cdot \frac{4 \cdot V_{O,max} \cdot I_O}{n \cdot \sqrt{2} \cdot V_{IN,min,rms}}
$$
  
= 1.204 \cdot \frac{4 \cdot 122V \cdot 0.15A}{0.85 \cdot (\sqrt{2} \cdot 195.5V)}  
= 0.375A

# 6.1.3 SELECTING THE SWITCHING FET

The voltage rating of the switching FET should be:

# **EQUATION 6-10:**

$$
BV_{DSS,min} = 1.3 \cdot (\sqrt{2} \cdot V_{IN,max,rms} + V_{O,max})
$$
  
= 1.3 \cdot (\sqrt{2} \cdot 264.5V + 122V) = 645V

A 650V rated switching FET should be chosen for this application.

The r.m.s current through the FET is:

# **EQUATION 6-11:**

$$
I_{Q,rms,max} =
$$
\n
$$
\frac{4 \cdot V_{O,max} \cdot I_{O}}{n \cdot (\sqrt{2} \cdot V_{IN,min,rms})} \cdot \sqrt{\frac{1}{3} \cdot \left(\frac{4 \cdot (\sqrt{2} \cdot V_{IN,min,rms})}{3 \cdot \pi \cdot V_{O,max}} + \frac{1}{2}\right)} =
$$
\n
$$
\frac{4 \cdot 122V \cdot 0.15A}{0.85 \cdot (\sqrt{2} \cdot 195.5)} \cdot \sqrt{\frac{1}{3} \cdot \left(\frac{4 \cdot (\sqrt{2} \cdot 195.5V)}{3 \cdot \pi \cdot 122V} + \frac{1}{2}\right)}
$$
\n
$$
= 217.48 \text{ mA}
$$

The Rds $_{0n}$  of the FET can be computed assuming a 3% power loss at maximum output power and minimum input voltage.

## **EQUATION 6-12:**

$$
Rds_{on, 25C} = \frac{0.03 \cdot P_{O, max}}{1.5 \cdot I_{O, rms}^2} = \frac{0.03 \cdot 18.3 W}{1.5 \cdot 0.217^2} = 7.77 \Omega
$$

The 1.5 factor in the denominator is used to account for the higher FET resistance in actual operation due to higher junction temperature.

## 6.1.4 SELECTING THE SWITCHING DIODE

The voltage rating of the switching diode should match or exceed the voltage rating of the switching FET. A high-speed diode with reverse recovery time in the order of 50 ns should be chosen for this application. The peak, r.m.s and average current through the diode can be computed using the following equations:

# **EQUATION 6-13:**

$$
I_{DBBT, avg} = I_O = 0.15A
$$

# **EQUATION 6-14:**

# **EQUATION 6-15:**

$$
I_{DBBT,max,rms} = \frac{4 \cdot V_{O,max} \cdot I_O}{n \cdot \sqrt{2} \cdot V_{IN,min,rms}} \cdot K_{ID}
$$

$$
= \frac{4 \cdot 122 V \cdot 0.15 A}{0.85 \cdot \sqrt{2} \cdot 195.5 V} \cdot 0.981 = 0.306 A
$$

# **EQUATION 6-16:**

$$
I_{DBBT, peak} = I_{L,max, pk} = 1.0A
$$

# 6.1.5 CHOOSING THE OUTPUT **CAPACITOR**

The output capacitor is chosen based on the maximum allowable line frequency ripple in the LED current. This can be computed if the desired flicker index is known.

<span id="page-12-0"></span>For a given instantaneous light output waveform (shown in [Figure](#page-12-0) 6-1), the flicker index can be computed to be:

#### **EQUATION 6-17:**

$$
FI = \frac{Area1}{(Area1) + (Area2)}
$$
  
where:  
Area1 = the area of the curve above the average  
Area2 = the area of the curve below the average

Assuming that the instantaneous light output is directly proportional to the instantaneous LED current, the flicker index can be computed from the instantaneous LED current waveform shown in [Figure](#page-12-0) 6-1.

#### **EQUATION 6-18:**

$$
FI = \frac{\Delta I_O}{2 \cdot \pi \cdot I_O}
$$
  
\n
$$
\Rightarrow \Delta I_O = 2 \cdot FI \cdot \pi \cdot I_O = 2 \cdot 0.15 \cdot \pi \cdot 0.15A = 0.14A
$$

The typical LED string dynamic resistance can be computed as:

#### **EQUATION 6-19:**

$$
R_{LED} = 0.05 \cdot \frac{V_{O, max}}{I_O} = 0.05 \cdot \frac{122V}{0.15A} = 40.67\Omega
$$

The corresponding line frequency peak-to-peak ripple in the output voltage is:

#### **EQUATION 6-20:**

$$
\Delta V_O = \Delta I_O \cdot R_{LED} = 0.14A \cdot 40.67\Omega = 5.69V
$$

The output capacitor is usually dominated by the low-frequency ripple component. It can be computed using the following equation:

# **EQUATION 6-21:**  $C_{O} = \frac{I_{O}}{4 \cdot \pi \cdot f_{L} \cdot \Delta V_{O}} = \frac{0.15A}{4 \cdot \pi \cdot 50 Hz \cdot 5.69V} = 42 \mu F$

Voltage rating of the output capacitor should be about 20% higher than the maximum output voltage.

## **EQUATION 6-22:**

$$
V_{CO} = 1.2 \cdot V_{O, max} = 1.2 \cdot 122V = 146V
$$

The r.m.s current through the output capacitor is:

#### **EQUATION 6-23:**

$$
I_{Co, rms} = \sqrt{I_{DBBT, max, rms}^2 - I_O^2} = \sqrt{0.305A^2 - 0.15A^2} = 0.265A
$$

#### 6.1.6 SELECTING THE INPUT CAPACITOR

The input capacitor is selected to reduce the input ripple voltage. A simple first-pass selection can be computed as:

#### **EQUATION 6-24:**

$$
C_{REC} = \frac{0.5 \cdot I_{L,max, pk} \cdot T_{ON, max}}{0.1 \cdot \sqrt{2} \cdot V_{IN, min, rms}}
$$

$$
= \frac{0.5 \cdot I A \cdot 10.2 \mu s}{0.1 \cdot (\sqrt{2} \cdot 195.5 V)} = 0.185 \mu F
$$

This capacitor will need to be adjusted in once a prototype is built. A large value will increase the THD where as a low value will affect the EMI performance.

## **6.2 Control Stage Design**

#### 6.2.1 SELECTING THE CURRENT SENSE RESISTOR

The current sense resistor value is set by the output current. The resistor's power rating is set by the inductor current.

#### **EQUATION 6-25:**

$$
R_{CS} = \frac{CS_{REF}}{I_O} = \frac{0.2V}{0.15A} = 1.33\Omega
$$
  

$$
P_{Rcs} = I_{L,rms}^2 \cdot R_{CS} = 0.375A^2 \cdot 1.33\Omega = 0.187W
$$

#### 6.2.2 SELECTING THE VALLEY SENSE **COMPONENTS**

The resistor used for detecting the valley is also used for over-voltage protection. Hence, the resistor should be chosen based on the over-voltage setting desired.

Assume a 10% headroom over the maximum output voltage to set the minimum over-voltage threshold. Then, the resistor is:

#### **EQUATION 6-26:**

$$
R_{VD} = \frac{1.1 \cdot V_{O, max} - V_{IND}}{I_{OCP, min}} = \frac{1.1 \cdot 122V - 4.3V}{350 \mu A} = 371 k\Omega
$$

Then maximum output voltage that can occur during over-voltage conditions is:

#### **EQUATION 6-27:**

$$
\begin{vmatrix} OVP_{max} = I_{OCP,max} \cdot R_{VD} + V_{IND} = 550 \mu A \cdot 371 k\Omega + 4.3 V \\ = 208 V \end{vmatrix}
$$

Note that since this is not a continuous operation, the voltage rating of the output capacitor should be chosen to withstand this voltage, but not to operate at this voltage continuously.

The diode in series with this resistor should be a 500 μA switching diode with a breakdown voltage of at least 400V (250V for a HV98100 design).

6.2.3 SELECTING THE START-UP NETWORK

The start-up resistor should be chosen based on the maximum start-up time that is allowable before the GATE starts switching. Note that selecting a shorter

#### <span id="page-14-2"></span>**EQUATION 6-29:**

start-up time will cause higher losses in the resistor during operation. The start-up time and power loss should be iterated until a reasonable compromise is achieved for both parameters.

The minimum capacitor at  $PV_{DD}$  required is 4.7 µF. In most cases this capacitor value is sufficient for hold-up.

Assuming a 100 ms start-up time  $(T<sub>STRT</sub>)$ , the start-up resistor can be computed as shown in [Equation](#page-14-1) 6-28.

#### <span id="page-14-1"></span>**EQUATION 6-28:**

$$
R_{HV} = \frac{\sqrt{2} \cdot V_{in, min, rms} - V_{DD, ON}}{C_{PVDD} \cdot V_{DD, ON}} + 200 \mu A = \frac{\sqrt{2} \cdot 195.5V - 16V}{\frac{4.7 \mu F \cdot 16V}{100ms} + 200 \mu A}
$$

$$
= 273 k\Omega
$$

The maximum power loss in the resistor occurs at high line and is shown in [Equation](#page-14-2) 6-29.

$$
P_{RHV, max} = \frac{\sqrt{2} \cdot V_{in, max, rms} \cdot (4 \cdot V_{O, max} + \pi \cdot \sqrt{2} \cdot V_{in, max, rms})}{2 \cdot \pi \cdot R_{HV}}
$$
  
= 
$$
\frac{\sqrt{2} \cdot 264.5V \cdot (4 \cdot 122V + \pi \cdot \sqrt{2} \cdot 264.5V)}{2 \cdot \pi \cdot 273k\Omega} = 0.363W
$$

The minimum average current supplied by RHV during operation is shown in [Equation](#page-14-3) 6-30.

#### <span id="page-14-3"></span>**EQUATION 6-30:**

$$
I_{RHV, min, avg} = \frac{2 \cdot \sqrt{2} \cdot V_{in, min, rms}}{\pi \cdot R_{HV}}
$$

$$
= \frac{2 \cdot \sqrt{2} \cdot 195.5V}{\pi \cdot 273k\Omega}
$$

$$
= 645 \mu A
$$

The diode in the start-up network  $(D_{HV})$  can be a simple 1N4148.

#### 6.2.4 SELECTING BOOTSTRAP **COMPONENTS**

The total current required by the IC during normal operation comes from two sources

- Current through  $R_{HV}$
- $\cdot$  Current through  $R_{\text{PVDD}}$

The current through  $R_{HV}$  resistor has been computed in [Equation](#page-14-1) 6-28. The average current supplied through  $R_{\text{PVDD}}$  is:

#### <span id="page-14-0"></span>**EQUATION 6-31:**

$$
I_{RPVDD, AVG} = \frac{1}{\pi} \cdot \int_{0}^{\pi} \left( \frac{V_O - PV_{DD}}{R_{PVDD}} \cdot \frac{\hat{V}_{IN} \cdot sin\theta}{V_O + \hat{V}_{IN} \cdot sin\theta} \right) d\theta
$$

However, the closed form solution for the integral in [Equation](#page-14-0) 6-31 is very complex. The equation can be simplified using a curve fit solution.

#### **EQUATION 6-32:**

$$
I_{RPVDD_{AVG}} = \frac{V_O - PV_{DD}}{R_{PVDD}} \cdot \left( 0.193 \cdot ln \left( \frac{\hat{V}_{IN}}{V_O} \right) + 0.3801 \right)
$$

This approximation is valid as long as

$$
2\leq \frac{\hat{V_{IN}}}{V_O} \leq 10
$$

Assuming we need a total current of about 4 mA during normal operation, the  $R_{\text{PVDD}}$  resistor can be chosen as:

#### **EQUATION 6-33:**

$$
R_{PVDD} =
$$
\n
$$
\frac{V_{O,min} - PV_{DD}}{(I_{PVDD} - I_{RHV})} \cdot \left( 0.193 \cdot ln \left( \frac{V_{IN}}{V_{O,min}} \right) + 0.3801 \right)
$$
\n
$$
= \frac{88V - 16V}{(4 mA - 645 \mu A)} \cdot \left( 0.193 \cdot ln \left( \frac{\sqrt{2} \cdot 195.5V}{88V} \right) + 0.3801 \right)
$$
\n
$$
= 12k\Omega
$$

The power dissipated in the  $R_{\text{PVDD}}$  resistor can be computed as:

#### **EQUATION 6-34:**

$$
\begin{aligned}\nI_{RPVDD,rms} &= \frac{V_O - PV_{DD}}{R_{PVDD}} \cdot \sqrt{(0.193 \cdot \ln\left(\frac{\hat{V}_{IN}}{V_O}\right) + 0.3801)} \\
&= \frac{88V - 16V}{12.9k\Omega} \cdot \sqrt{(0.193 \cdot \ln\left(\frac{\sqrt{2} \cdot 195.5V}{88V}\right) + 0.3801)} \\
&= 4.33 \text{ mA} \\
P_{RPVDD} &= I_{RPVDD,rms}^2 \cdot R_{PVDD} \\
&= 4.33 \text{ mA}^2 \cdot 12.9 k\Omega = 0.242 W\n\end{aligned}
$$

The average current drawn by the IC is not easy to estimate. It is recommended to start with an assumed higher value for the current consumed by the IC (4 mA-5 mA) and increase  $R_{\text{PVDD}}$  by trial and error.

The bootstrap diode should have a voltage rating of at least 400V (at least 250V for an HV98100 design) and an average current rating of about 5 mA. This should be a switching diode with a very low-junction capacitance (< 10 pF preferable).

## 6.2.5 CHOOSING THE COMPENSATION CAPACITOR

The compensation capacitor serves two functions in a power factor correction circuit:

- maintain loop stability
- reduce third harmonic distortion in the input current.

The capacitor can be chosen based on either criteria. For this design example, the capacitor is chosen based on the third harmonic distortion criterion. This criterion leads to a larger compensation capacitor value which also ensures stability in most cases.

The second harmonic component of the COMP voltage causes third harmonic distortion in the input current. The criterion used to design the compensation capacitor is that the second harmonic peak-to-peak voltage in COMP voltage is 2% of the DC component of the COMP voltage.

[Equation](#page-15-0) 6-35 shows the relation between the input current and the DC component of the COMP voltage.

#### <span id="page-15-0"></span>**EQUATION 6-35:**

Substituting values in [Equation](#page-15-0) 6-35:

## **EQUATION 6-36:**

$$
COMP = \frac{2 \cdot 2.79mH \cdot 110mA \cdot 2.5V}{2 \cdot 195.5V \cdot 1.25 \,\mu s} = 3.14V
$$

The compensation capacitor can be computed as:

## **EQUATION 6-37:**

$$
C_{COMP} = \frac{\Delta I_O \cdot R_{CS} \cdot g_m}{2 \cdot (2 \cdot \pi \cdot f_L) \cdot \Delta V_{COMP}} =
$$
  

$$
\frac{0.14A \cdot 1.3\Omega \cdot 230\mu \frac{A}{V}}{2 \cdot (2 \cdot \pi \cdot 50 Hz) \cdot 0.06V} = 1.11 \mu F
$$

**Note:** The design of the EMI filter is beyond the scope of this design example. The design example is intended to provide a first pass design that can be further optimized in hardware.

# **7.0 PACKAGING INFORMATION**

# **7.1 Package Marking Information**

# 6-Lead Plastic Small Outline Transistor (CH) [SOT-23]

Note: For the most current package drawings, please see the Microchip Packaging Specification located at http://www.microchip.com/packaging

#### Notes:

- 1. Dimensions D and E1 do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.127 mm per side.
- 2. Dimensioning and tolerancing per ASME Y14.5M.

BSC: Basic Dimension. Theoretically exact value shown without tolerances.

Microchip Technology Drawing C04-028B

# 6-Lead Plastic Small Outline Transistor (CH) [SOT-23]

**Note:** For the most current package drawings, please see the Microchip Packaging Specification located at http://www.microchip.com/packaging

Notes:

1. Dimensioning and tolerancing per ASME Y14.5M

BSC: Basic Dimension. Theoretically exact value shown without tolerances.

**NOTES:**

#### **Note the following details of the code protection feature on Microchip devices:**

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE**.** Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights unless otherwise stated.

*Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.*
